## Chapter 4

## Character Properties

#### Abstract

Disclaimer The content of all character property tables has been verified as far as possible by the Unicode Consortium. However, in case of conflict, the most authoritative version of the information for Version 5.2.0 is that supplied in the Unicode Character Database on the Unicode Web site. The contents of all the tables in this chapter may be superseded or augmented by information in future versions of the Unicode Standard.

The Unicode Standard associates a rich set of semantics with characters and, in some instances, with code points. The support of character semantics is required for conformance; see Section 3.2, Conformance Requirements. Where character semantics can be expressed formally, they are provided as machine-readable lists of character properties in the Unicode Character Database (UCD). This chapter gives an overview of character properties, their status and attributes, followed by an overview of the UCD and more detailed notes on some important character properties. For a further discussion of character properties, see Unicode Technical Report \#23, "Unicode Character Property Model."
Status and Attributes. Character properties may be normative, informative, contributory, or provisional. Normative properties are those required for conformance. The following sections discuss important properties identified by their status. Many Unicode character properties can be overridden by implementations as needed. Section 3.2, Conformance Requirements, specifies when such overrides must be documented. A few properties, such as Noncharacter_Code_Point, may not be overridden. See Section 3.5, Properties, for the formal discussion of the status and attributes of properties.

Consistency of Properties. The Unicode Standard is the product of many compromises. It has to strike a balance between uniformity of treatment for similar characters and compatibility with existing practice for characters inherited from legacy encodings. Because of this balancing act, one can expect a certain number of anomalies in character properties. For example, some pairs of characters might have been treated as canonical equivalents but are left unequivalent for compatibility with legacy differences. This situation pertains to $\mathrm{U}+00 \mathrm{~B} 5 \mu$ micro sign and $\mathrm{U}+03 \mathrm{BC} \mu$ greek small letter mu, as well as to certain Korean jamo.

In addition, some characters might have had properties differing in some ways from those assigned in this standard, but those properties are left as is for compatibility with existing practice. This situation can be seen with the halfwidth voicing marks for Japanese ( $\mathrm{U}+\mathrm{FF} 9 \mathrm{E}$ halfwidth katakana voiced sound mark and U+FF9F halfwidth kataKANA SEMI-voiced sound mark), which might have been better analyzed as spacing combining marks, and with the conjoining Hangul jamo, which might have been better analyzed as an initial base character followed by formally combining medial and final characters. In the interest of efficiency and uniformity in algorithms, implementations may take advantage of such reanalyses of character properties, as long as this does not conflict with
the conformance requirements with respect to normative properties. See Section 3.5, Properties; Section 3.2, Conformance Requirements; and Section 3.3, Semantics, for more information.

### 4.1 Unicode Character Database

The Unicode Character Database (UCD) consists of a set of files that define the Unicode character properties and internal mappings. For each property, the files determine the assignment of property values to each code point. The UCD also supplies recommended property aliases and property value aliases for textual parsing and display in environments such as regular expressions.

The properties include the following:

- Name
- General Category (basic partition into letters, numbers, symbols, punctuation, and so on)
- Other important general characteristics (whitespace, dash, ideographic, alphabetic, noncharacter, deprecated, and so on)
- Display-related properties (bidirectional class, shaping, mirroring, width, and so on)
- Casing (upper, lower, title, folding-both simple and full)
- Numeric values and types
- Script and Block
- Normalization properties (decompositions, decomposition type, canonical combining class, composition exclusions, and so on)
- Age (version of the standard in which the code point was first designated)
- Boundaries (grapheme cluster, word, line, and sentence)

See Unicode Standard Annex \#44, "Unicode Character Database," for more details on the character properties and their values, the status of properties, their distribution across data files, and the file formats.

Unihan Database. In addition, a large number of properties specific to CJK ideographs are defined in the Unicode Character Database. These properties include source information, radical and stroke counts, phonetic values, meanings, and mappings to many East Asian standards. The values for all these properties are listed in the file Unihan.zip, also known as the Unihan Database. For a complete description and documentation of the properties themselves, see Unicode Standard Annex \#38, "Unicode Han Database (Unihan)." (See also "Online Unihan Database" in Section B.6, Other Unicode Online Resources.)
Many properties apply to both ideographs and other characters. These are not specified in the Unihan Database.
Stability. While the Unicode Consortium strives to minimize changes to character property data, occasionally character properties must be updated. When this situation occurs, a new version of the Unicode Character Database is created, containing updated data files. Data file changes are associated with specific, numbered versions of the standard; character properties are never silently corrected between official versions.

Each version of the Unicode Character Database, once published, is absolutely stable and will never change. Implementations or specifications that refer to a specific version of the UCD can rely upon this stability. Detailed policies on character encoding stability as they relate to properties are found on the Unicode Web site. See the subsection "Policies" in Section B.6, Other Unicode Online Resources. See also the discussion of versioning and stability in Section 3.1, Versions of the Unicode Standard.

Aliases. Character properties and their values are given formal aliases to make it easier to refer to them consistently in specifications and in implementations, such as regular expressions, which may use them. These aliases are listed exhaustively in the Unicode Character Database, in the data files PropertyAliases.txt and PropertyValueAliases.txt.
Many of the aliases have both a long form and a short form. For example, the General Category has a long alias "General_Category" and a short alias "gc". The long alias is more comprehensible and is usually used in the text of the standard when referring to a particular character property. The short alias is more appropriate for use in regular expressions and other algorithmic contexts.

In comparing aliases programmatically, loose matching is appropriate. That entails ignoring case differences and any whitespace, underscore, and hyphen characters. For example, "GeneralCategory", "general_category", and "GENERAL-CATEGORY" would all be considered equivalent property aliases. See Unicode Standard Annex \#44, "Unicode Character Database," for further discussion of property and property value matching.
For each character property whose values are not purely numeric, the Unicode Character Database provides a list of value aliases. For example, one of the values of the Line_Break property is given the long alias "Open_Punctuation" and the short alias "OP".
Property aliases and property value aliases can be combined in regular expressions that pick out a particular value of a particular property. For example, " $\mid p\{l b=O P\}$ " means the Open_Punctuation value of the Line_Break property, and " $\operatorname{p}\{\mathrm{gc}=\mathrm{Lu}\}$ " means the Uppercase_Letter value of the General_Category property.

Property aliases define a namespace. No two character properties have the same alias. For each property, the set of corresponding property value aliases constitutes its own namespace. No constraint prevents property value aliases for different properties from having the same property value alias. Thus " B " is the short alias for the Paragraph_Separator value of the Bidi_Class property; " $B$ " is also the short alias for the Below value of the Canonical_Combining_Class property. However, because of the namespace restrictions, any combination of a property alias plus an appropriate property value alias is guaranteed to constitute a unique string, as in " $\mid \mathrm{p}\{\mathrm{b} c=\mathrm{B}\}$ " versus " $\backslash \mathrm{p}\{\mathrm{ccc}=\mathrm{B}\}$ ".

For a recommended use of property and property value aliases, see Unicode Technical Standard \#18, "Unicode Regular Expressions." Aliases are also used for normatively referencing properties, as described in Section 3.1, Versions of the Unicode Standard.

UCD in XML. Starting with Unicode Version 5.1.0, the complete Unicode Character Database is also available formatted in XML. This includes both the non-Han part of the Unicode Character Database and all of the content of the Unihan Database. For details regarding the XML schema, file names, grouping conventions, and other considerations, see Unicode Standard Annex \#42, "Unicode Character Database in XML."

Online Availability. All versions of the UCD are available online on the Unicode Web site. See the subsections "Online Unicode Character Database" and "Online Unihan Database" in Section B.6, Other Unicode Online Resources.

### 4.2 Case-Normative

Case is a normative property of characters in certain alphabets whereby characters are considered to be variants of a single letter. These variants, which may differ markedly in shape and size, are called the uppercase letter (also known as capital or majuscule) and the lowercase letter (also known as small or minuscule). The uppercase letter is generally larger than the lowercase letter.
Because of the inclusion of certain composite characters for compatibility, such as U+01F1 latin capital letter dz, a third case, called titlecase, is used where the first character of a word must be capitalized. An example of such a character is U+01F2 Latin Capital Letter d with small letter $z$. The three case forms are UPPERCASE, Titlecase, and lowercase.

For those scripts that have case (Latin, Greek, Coptic, Cyrillic, Glagolitic, Armenian, Deseret, and archaic Georgian), uppercase characters typically contain the word capital in their names. Lowercase characters typically contain the word small. However, this is not a reliable guide. The word small in the names of characters from scripts other than those just listed has nothing to do with case. There are other exceptions as well, such as small capital letters that are not formally uppercase. Some Greek characters with capital in their names are actually titlecase. (Note that while the archaic Georgian script contained upper- and lowercase pairs, they are not used in modern Georgian. See Section 7.7, Georgian.)

## Definitions of Case and Casing

The Unicode Standard has more than one formal definition of lowercase, uppercase, and related casing processes. This is the result of the inherent complexity of case relationships and of defining case-related behavior on the basis of individual character properties. This section clarifies the distinctions involved in the formal definition of casing in the standard. The additional complications for titlecase are omitted from the discussion; titlecase distinctions apply only to a handful of compatibility characters.
The first set of values involved in the definition of case are based on the General_Category property in UnicodeData.txt. The relevant values are General_Category=Ll (Lowercase_Letter) and General_Category=Lu (Uppercase_Letter). For most ordinary letters of bicameral scripts such as Latin, Greek, and Cyrillic, these values are obvious and non-problematical. However, the General_Category property is, by design, a partition of the Unicode codespace. This means that each Unicode character can only have one General_Category value, which results in some odd edge cases for modifier letters, letterlike symbols and letterlike numbers. As a consequence, not every Unicode character that looks like a lowercase character necessarily ends up with General_Category= Ll , and not every Unicode character that looks like an uppercase character ends up with General_Category=Lu.
The second set of definitions relevant to case consist of the derived binary properties, Lowercase and Uppercase, specified in DerivedCoreProperties.txt in the Unicode Character Database. Those derived properties augment the General_Category values by adding the additional characters that ordinary users think of as being lowercase or uppercase, based primarily on their letterforms. The additional characters are included in the derivations by means of the contributory properties, Other_Lowercase and Other_Uppercase, defined in PropList.txt. For example, Other_Lowercase adds the various modifier letters that are letterlike in shape, the circled lowercase letter symbols, and the compatibility lowercase Roman numerals. Other_Uppercase adds the circled uppercase letter symbols, and the compatibility uppercase Roman numerals.

A third set of definitions for case is fundamentally different in kind, and does not consist of character properties at all. The functions isLowercase and isUppercase are string functions returning a binary True/False value. These functions are defined in Section 3.13, Default Case Algorithms, and depend on case mapping relations, rather than being based on letterforms per se. Basically, isLowercase is True for a string if the result of applying the toLowercase mapping operation for a string is the same as the string itself.
Table 4-1 illustrates the various possibilities for how these definitions interact, as applied to exemplary single characters or single character strings.

Table 4-1. Relationship of Casing Definitions

| Code | Character | gc | Lowercase | Uppercase | isLowerCase(S) | isUpperCase(S) |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 0068 | h | Ll | True | False | True | False |
| 0048 | H | Lu | False | True | False | True |
| 24D7 | ® | So | True | False | True | False |
| 24BD | ® | So | False | True | False | True |
| 02B0 | h | Lm | True | False | True | True |
| 1D34 | H | Lm | True | False | True | True |
| 02BD | ' | Lm | False | False | True | True |

Note that for "caseless" characters, such as U+02B0, U+1D34, and U+02BD, isLowerCase and isUpperCase are both True, because the inclusion of a caseless letter in a string is not criterial for determining the casing of the string-a caseless letter always case maps to itself.
On the other hand, all modifier letters derived from letter shapes are also notionally lowercase, whether the letterform itself is a minuscule or a majuscule in shape. Thus U+1D34 MODIFIER LETTER CAPITAL H is actually Lowercase=True. Other modifier letters not derived from letter shapes, such as $\mathrm{U}+02 \mathrm{BD}$, are neither Lowercase nor Uppercase.

The string functions isLowerCase and isUpperCase also apply to strings longer than one character, of course, for which the character properties General_Category, LowerCase, and Uppercase are not relevant. In Table 4-2, the string function isTitleCase is also illustrated, to show its applicability for the same strings.

Table 4-2. Case Function Values for Strings

| Codes | String | isLowerCase(S) | isUpperCase(S) | isTitleCase(S) |
| :---: | :---: | :---: | :---: | :---: |
| 00680068 | hh | True | False | False |
| 00480048 | HH | False | True | False |
| 00480068 | Hh | False | False | True |
| 00680048 | hH | False | False | False |

Programmers concerned with manipulating Unicode strings should generally be dealing with the string functions such as isLowerCase (and its functional cousin, toLowerCase), unless they are working directly with single character properties. Care is always advised, however, when dealing with case in the Unicode Standard, as expectations based simply on the behavior of the basic Latin alphabet (A..Z, a..z) do not generalize easily across the entire repertoire of Unicode characters, and because case for modifier letters, in particular, can result in unexpected behavior.

## Case Mapping

The default case mapping tables defined in the Unicode Standard are normative, but may be overridden to match user or implementation requirements. The Unicode Character Database contains four files with case mapping information, as shown in Table 4-3. Full case mappings for Unicode characters are obtained by using the basic mappings from UnicodeData.txt and extending or overriding them where necessary with the mappings from SpecialCasing.txt. Full case mappings may depend on the context surrounding the character in the original string.

Some characters have a "best" single-character mapping in UnicodeData.txt as well as a full mapping in SpecialCasing.txt. Any character that does not have a mapping in these files is considered to map to itself. For more information on case mappings, see Section 5.18, Case Mappings.

Table 4-3. Sources for Case Mapping Information

| File Name | Description |
| :--- | :--- |
| UnicodeData.txt | Contains the case mappings that map to a single character. These do not <br> increase the length of strings, nor do they contain context-dependent map- <br> pings. |
| SpecialCasing.txt | Contains additional case mappings that map to more than one character, such <br> as " $ß$ " to "SS". Also contains context-dependent mappings, with flags to distin- <br> guish them from the normal mappings, as well as some locale-dependent <br> mappings. |
| CaseFolding.txt | Contains data for performing locale-independent case folding, as described in <br> "Caseless Matching," in Section 5.18, Case Mappings. |
| PropList.txt | Contains the definition of the property Soft_Dotted, which is used in the con- <br> text specification for casing. See D138 in Section 3.13, Default Case Algorithms. |

The single-character mappings in UnicodeData.txt are insufficient for languages such as German. Therefore, only legacy implementations that cannot handle case mappings that increase string lengths should use UnicodeData.txt case mappings alone.

A set of charts that show the latest case mappings is also available on the Unicode Web site. See "Charts" in Section B.6, Other Unicode Online Resources.

### 4.3 Combining Classes-Normative

Each combining character has a normative canonical combining class. This class is used with the Canonical Ordering Algorithm to determine which combining characters interact typographically and to determine how the canonical ordering of sequences of combining characters takes place. Class zero combining characters act like base letters for the purpose of determining canonical order. Combining characters with non-zero classes participate in reordering for the purpose of determining the canonical order of sequences of characters. (See Section 3.11, Normalization Forms, for the specification of the algorithm.)

The list of combining characters and their canonical combining class appears in the Unicode Character Database. Most combining characters are nonspacing.

The canonical order of character sequences does not imply any kind of linguistic correctness or linguistic preference for ordering of combining marks in sequences. For more information on rendering combining marks, see Section 5.13, Rendering Nonspacing Marks.

Class zero combining marks are never reordered by the Canonical Ordering Algorithm. Except for class zero, the exact numerical values of the combining classes are of no impor-
tance in canonical equivalence, although the relative magnitude of the classes is significant. For example, it is crucial that the combining class of the cedilla be lower than the combining class of the dot below, although their exact values of 202 and 220 are not important for implementations.

Certain classes tend to correspond with particular rendering positions relative to the base character, as shown in Figure 4-1.

Figure 4-1. Positions of Common Combining Marks

## Reordrant, Split, and Subjoined Combining Marks

In some scripts, the rendering of combining marks is notably complex. This is true in particular of the Brahmi-derived scripts of South and Southeast Asia, whose vowels are often encoded as class zero combining marks in the Unicode Standard, known as matras for the Indic scripts.

In the case of simple combining marks, as for the accent marks of the Latin script, the normative Unicode combining class of that combining mark typically corresponds to its positional placement with regard to a base letter, as described earlier. However, in the case of the combining marks representing vowels (and sometimes consonants) in the Brahmiderived scripts, all of the combining marks are given the normative combining class of zero, regardless of their positional placement within an aksara. The placement and rendering of a class zero combining mark cannot be derived from its combining class alone, but rather depends on having more information about the particulars of the script involved. In some instances, the position may migrate in different historical periods for a script or may even differ depending on font style.

Such matters are not treated as normative character properties in the Unicode Standard, because they are more properly considered properties of the glyphs and fonts used for rendering. However, to assist implementers, this section subcategorizes some class zero combining marks for Brahmi-derived scripts, pointing out significant types that need to be handled consistently.
Reordrant Class Zero Combining Marks. In many instances in Indic scripts, a vowel is represented in logical order after the consonant of a syllable, but is displayed before (to the left of) the consonant when rendered. Such combining marks are termed reordrant to reflect their visual reordering to the left of a consonant (or, in some instances, a consonant cluster). Special handling is required for selection and editing of these marks. In particular, the possibility that the combining mark may be reordered left past a cluster, and not simply past the immediate preceding character in the backing store, requires attention to the details for each script involved.

The visual reordering of these reordrant class zero combining marks has nothing to do with the reordering of combining character sequences in the Canonical Ordering Algorithm. All of these marks are class zero and thus are never reordered by the Canonical Ordering Algorithm for normalization. The reordering is purely a presentational issue for glyphs during rendering of text.

Table 4-4 lists reordrant class zero combining marks in the Unicode Standard.
Table 4-4. Class Zero Combining Marks—Reordrant

| Script | Code Points |
| :--- | :--- |
| Devanagari | 093F, 094E |
| Bengali | 09BF, 09C7, 09C8 |
| Gurmukhi | 0A3F |
| Gujarati | 0ABF |
| Oriya | 0B47 |
| Tamil | 0BC6, 0BC7, 0BC8 |
| Malayalam | 0D46, 0D47, 0D48 |
| Sinhala | 0DD9, 0DDA, 0DDB |
| Myanmar | 1031, 1084 |
| Khmer | 17C1, 17C2, 17C3 |
| New Tai Lue | 19B5, 19B6, 19B7, 19BA |
| Buginese | 1A19, 1A1B |
| Tai Tham | 1A55, 1A6E, 1A6F, 1A70, 1A71, 1A72 |
| Balinese | 1B3E, 1B3F |
| Sundanese | 1BA6 |
| Lepcha | 1C27, 1C28, 1C29, 1C34, 1C35 |
| Javanese | A9BA, A9BB |
| Cham | AA2F, AA30, AA34 |
| Kaithi | 110B1 |

In addition, there are historically related vowel characters in the Thai, Lao, and Tai Viet scripts that, for legacy reasons, are not treated as combining marks. Instead, for Thai, Lao, and Tai Viet these vowels are represented in the backing store in visual order and require no reordering for rendering. The trade-off is that they have to be rearranged logically for searching and sorting. Because of that processing requirement, these characters are given a formal character property assignment, the Logical_Order_Exception property, as listed in Table 4-5. See PropList.txt in the Unicode Character Database.

Table 4-5. Thai, Lao, and Tai Viet Logical Order Exceptions

| Script | Code Points |
| :--- | :--- |
| Thai | 0E40..0E44 |
| Lao | $0 \mathrm{EC} 0 . .0 \mathrm{EC} 4$ |
| Tai Viet | AAB5, AAB6, AAB9, AABB, AABC |

Split Class Zero Combining Marks. In addition to the reordrant class zero combining marks, there are a number of class zero combining marks whose representative glyph typically consists of two parts, which are split into different positions with respect to the consonant (or consonant cluster) in an aksara. Sometimes these glyphic pieces are rendered both to the left and the right of a consonant. Sometimes one piece is rendered above or below the consonant and the other piece is rendered to the left or the right. Particularly in the instances where some piece of the glyph is rendered to the left of the consonant, these split class zero combining marks pose similar implementation problems as for the reordrant marks.

Table 4-6 lists split class zero combining marks in the Unicode Standard, subgrouped by positional patterns.

One should pay very careful attention to all split class zero combining marks in implementations. Not only do they pose issues for rendering and editing, but they also often have

Table 4-6. Class Zero Combining Marks—Split

| Glyph Positions | Script | Code Points |
| :---: | :---: | :---: |
| Left and right | Bengali | 09CB, 09CC |
|  | Oriya | 0B4B |
|  | Tamil | 0BCA, 0BCB, 0BCC |
|  | Malayalam | 0D4A, 0D4B, 0D4C |
|  | Sinhala | 0DDC, 0DDE |
|  | Khmer | 17C0, 17C4, 17C5 |
|  | Balinese | 1B40, 1B41 |
| Left and top | Oriya | 0B48 |
|  | Sinhala | 0DDA |
|  | Khmer | 17BE |
| Left, top, and right | Oriya | 0B4C |
|  | Sinhala | 0DDD |
|  | Khmer | 17BF |
| Top and right | Oriya | 0B57 |
|  | Kannada | 0CC0, 0CC7, 0CC8, 0CCA, 0ССВ |
|  | Limbu | 1925, 1926 |
|  | Balinese | 1B43 |
| Top and bottom | Telugu | 0C48 |
|  | Tibetan | 0F73, 0F76, 0F77, 0F78, 0F79, 0F81 |
|  | Balinese | 1B3C |
| Top, bottom, and right | Balinese | 1B3D |
| Bottom and right | Balinese | 1B3B |

canonical equivalences defined involving the separate pieces, when those pieces are also encoded as characters. As a consequence, the split combining marks may constitute exceptional cases under normalization. Some of the Tibetan split combining marks are deprecated.

The split vowels also pose difficult problems for understanding the standard, as the phonological status of the vowel phonemes, the encoding status of the characters (including any canonical equivalences), and the graphical status of the glyphs are easily confused, both for native users of the script and for engineers working on implementations of the standard.
Subjoined Class Zero Combining Marks. Brahmi-derived scripts that are not represented in the Unicode Standard with a virama may have class zero combining marks to represent subjoined forms of consonants. These correspond graphologically to what would be represented by a sequence of virama + consonant in other related scripts. The subjoined consonants do not pose particular rendering problems, at least not in comparison to other combining marks, but they should be noted as constituting an exception to the normal pattern in Brahmi-derived scripts of consonants being represented with base letters. This exception needs to be taken into account when doing linguistic processing or searching and sorting.
Table 4-7 lists subjoined class zero combining marks in the Unicode Standard.
Table 4-7. Class Zero Combining Marks—Subjoined

| Script | Code Points |
| :--- | :--- |
| Tibetan | 0F90..0F97, 0F99..0FBC |
| Limbu | 1929, 192A, 192B |

These Limbu consonants, while logically considered subjoined combining marks, are rendered mostly at the lower right of a base letter, rather than directly beneath them.

Strikethrough Class Zero Combining Marks. The Kharoshthi script is unique in having some class zero combining marks for vowels that are struck through a consonant, rather than being placed in a position around the consonant. These are also called out in Table 4-8 specifically as a warning that they may involve particular problems for implementations.

Table 4-8. Class Zero Combining Marks—Strikethrough

| Script | Code Points |
| :--- | :---: |
| Kharoshthi | 10A01, 10A06 |

### 4.4 Directionality—Normative

Directional behavior is interpreted according to the Unicode Bidirectional Algorithm (see Unicode Standard Annex \#9, "Unicode Bidirectional Algorithm"). For this purpose, all characters of the Unicode Standard possess a normative directional type, defined by the Bidi_Class (bc) property in the Unicode Character Database. The directional types left-toright and right-to-left are called strong types, and characters of these types are called strong directional characters. Left-to-right types include most alphabetic and syllabic characters as well as all Han ideographic characters. Right-to-left types include the letters of predominantly right-to-left scripts, such as Arabic, Hebrew, and Syriac, as well as most punctuation specific to those scripts. In addition, the Unicode Bidirectional Algorithm uses weak types and neutrals. Interpretation of directional properties according to the Unicode Bidirectional Algorithm is needed for layout of right-to-left scripts such as Arabic and Hebrew.

### 4.5 General Category-Normative

The Unicode Character Database defines a General_Category property for all Unicode code points. The General_Category value for a character serves as a basic classification of that character, based on its primary usage. The property extends the widely used subdivision of ASCII characters into letters, digits, punctuation, and symbols-a useful classification that needs to be elaborated and further subdivided to remain appropriate for the larger and more comprehensive scope of the Unicode Standard.
Each Unicode code point is assigned a General_Category value. Each value of the General_Category is given a two-letter property value alias, where the first letter gives information about a major class and the second letter designates a subclass of that major class. In each class, the subclass "other" merely collects the remaining characters of the major class. For example, the subclass "No" (Number, other) includes all characters of the Number class that are not a decimal digit or letter. These characters may have little in common besides their membership in the same major class.

Table 4-9 enumerates the General_Category values, giving a short description of each value. See Table 2-3 for the relationship between General_Category values and basic types of code points.

There are several other conventions for how General_Category values are assigned to Unicode characters. Many characters have multiple uses, and not all such uses can be captured by a single, simple partition property such as General_Category. Thus, many letters often serve dual functions as numerals in traditional numeral systems. Examples can be found in the Roman numeral system, in Greek usage of letters as numbers, in Hebrew, and similarly

Table 4-9. General Category

| Lu | $=$ Letter, uppercase |
| :--- | :--- |
| Ll | $=$ Letter, lowercase |
| Lt | $=$ Letter, titlecase |
| $\mathrm{Lm}=$ Letter, modifier |  |
| Lo | $=$ Letter, other |
| $\mathrm{Mn}=$ Mark, nonspacing |  |
| $\mathrm{Mc}=$ Mark, spacing combining |  |
| $\mathrm{Me}=$ Mark, enclosing |  |
| $\mathrm{Nd}=$ Number, decimal digit |  |
| $\mathrm{Nl}=$ Number, letter |  |

for many scripts. In such cases the General_Category is assigned based on the primary letter usage of the character, even though it may also have numeric values, occur in numeric expressions, or be used symbolically in mathematical expressions, and so on.
The General_Category $\mathrm{gc}=\mathrm{Nl}$ is reserved primarily for letterlike number forms which are not technically digits. For example, the compatibility Roman numeral characters, $\mathrm{U}+2160 . . \mathrm{U}+217 \mathrm{~F}$, all have $\mathrm{gc}=\mathrm{Nl}$. Because of the compatibility status of these characters, the recommended way to represent Roman numerals is with regular Latin letters ( $\mathrm{gc}=\mathrm{Ll}$ or $\mathrm{gc}=\mathrm{Lu})$. These letters derive their numeric status from conventional usage to express Roman numerals, rather than from their Generic_Category value.

Currency symbols ( $\mathrm{gc}=\mathrm{Sc}$ ), by contrast, are given their General_Category value based entirely on their function as symbols for currency, even though they are often derived from letters and may appear similar to other diacritic-marked letters that get assigned one of the letter-related General_Category values.
Pairs of opening and closing punctuation are given their General_Category values (gc=Ps for opening and $\mathrm{gc}=\mathrm{Pe}$ for closing) based on the most typical usage and orientation of such pairs. Occasional usage of such punctuation marks unpaired or in opposite orientation certainly occurs, however, and is in no way prevented by their General_Category values.
Similarly, characters whose General_Category identifies them primarily as a symbol or as a mathematical symbol may function in other contexts as punctuation or even paired punc-
tuation. The most obvious such case is for U+003C " $<$ " Less-than sign and U+003E ">" greater-than sign. These are given the General_Category gc=Sm because their primary identity is as mathematical relational signs. However, as is obvious from HTML and XML, they also serve ubiquitously as paired bracket punctuation characters in many formal syntaxes.

A common use of the General_Category of a Unicode character is to assist in determination of boundaries in text, as in Unicode Standard Annex \#29, "Unicode Text Segmentation." Other common uses include determining language identifiers for programming, scripting, and markup, as in Unicode Standard Annex \#31, "Unicode Identifier and Pattern Syntax," and in regular expression languages such as Perl. For more information, see Unicode Technical Standard \#18, "Unicode Regular Expressions."

This property is also used to support common APIs such as isDigit(). Common functions such as isLetter () and isUppercase () do not extend well to the larger and more complex repertoire of Unicode. While it is possible to naively extend these functions to Unicode using the General_Category and other properties, they will not work for the entire range of Unicode characters and range of tasks for which people use them. For more appropriate approaches, see Unicode Standard Annex \#31, "Unicode Identifier and Pattern Syntax"; Unicode Standard Annex \#29, "Unicode Text Segmentation"; Section 5.18, Case Mappings; and Section 4.10, Letters, Alphabetic, and Ideographic.

### 4.6 Numeric Value-Normative

Numeric value is a normative property of characters that represent numbers. This group includes characters such as fractions, subscripts, superscripts, Roman numerals, currency numerators, encircled numbers, and script-specific digits. In many traditional numbering systems, letters are used with a numeric value. Examples include Greek and Hebrew letters as well as Latin letters used in outlines (II.A.1.b). These special cases are not included here as numbers to prevent simplistic parsers from treating these letters numerically by mistake.
Decimal digits form a large subcategory of numbers consisting of those digits that can be used to form decimal-radix numbers. They include script-specific digits, but exclude characters such as Roman numerals and Greek acrophonic numerals. (Note that $\langle 1,5\rangle=15=$ fifteen, but $\langle\mathrm{I}, \mathrm{V}\rangle=\mathrm{IV}=$ four.) Decimal digits also exclude the compatibility subscript or superscript digits to prevent simplistic parsers from misinterpreting their values in context. Numbers other than decimal digits can be used in numerical expressions and may be interpreted by a numeric parser, but it is up to the implementation to determine such specialized uses.

The Unicode Standard assigns distinct codes to the particular digits that are specific to a given script. Examples are the digits used with the Arabic script or those of the Indic scripts. For naming conventions relevant to Arabic digits, see the introduction to Section 8.2, Arabic.
The Unicode Character Database gives the numeric values of Unicode characters that normally represent numbers.

## Ideographic Numeric Values

CJK ideographs also may have numeric values. The primary numeric ideographs are shown in Table 4-10. When used to represent numbers in decimal notation, zero is represented by $\mathrm{U}+3007$. Otherwise, zero is represented by $\mathrm{U}+96 \mathrm{~F} 6$.

Ideographic accounting numbers are commonly used on checks and other financial instruments to minimize the possibilities of misinterpretation or fraud in the representation of

Table 4-10. Primary Numeric Ideographs

| Code Point | Value |
| :--- | :--- |
| U+96F6 | 0 |
| U+4E00 | 1 |
| U+4E8C | 2 |
| U+4099 | 3 |
| U+56DB | 4 |
| U+4E94 | 5 |
| U+516D | 6 |
| U+4E03 | 7 |
| U+516B | 8 |
| U+4E5D | 9 |
| U+5341 | 10 |
| U+767E | 100 |
| U+5343 | 1,000 |
| U+4E07 | 10,000 |
| U+5104 | $100,000,000(10,000 \times 10,000)$ |
| U+4EBF | $100,000,000(10,000 \times 10,000)$ |
| U+5146 | $1,000,000,000,000(10,000 \times 10,000 \times 10,000)$ |

numerical values. The set of accounting numbers varies somewhat between Japanese, Chinese, and Korean usage. Table 4-11 gives a fairly complete listing of the known accounting characters. Some of these characters are ideographs with other meanings pressed into service as accounting numbers; others are used only as accounting numbers.

Table 4-11. Ideographs Used as Accounting Numbers

| Number | Multiple Uses | Accounting Use Only |
| :--- | :--- | :--- |
| 1 | U+58F9, U+58F1 | U+5F0C |
| 2 |  | U+8CAE, U+8CB3, U+8D30, U+5F10, U+5F0D |
| 3 | U+53C3, U+53C2 | U+53C1, U+5F0E |
| 4 | U+8086 |  |
| 5 | U+4F0D |  |
| 6 | U+9678, U+9646 |  |
| 7 | U+67D2 |  |
| 8 | U+634C |  |
| 9 | U+7396 |  |
| 10 | U+62FE | U+4F70 |
| 100 | U+964C |  |
| 1,000 | U+4EDF |  |
| 10,000 | U+842C |  |

In Japan, $\mathrm{U}+67 \mathrm{D} 2$ is also pronounced urusi, meaning "lacquer," and is treated as a variant of the standard character for "lacquer," U+6F06.
The Unihan Database gives the most up-to-date and complete listing of primary numeric ideographs and ideographs used as accounting numbers, including those for CJK repertoire extensions beyond the Unified Repertoire and Ordering. See Unicode Standard Annex \#38, "Unicode Han Database (Unihan)," for more details.

### 4.7 Bidi Mirrored-Normative

Bidi Mirrored is a normative property of characters such as parentheses, whose images are mirrored horizontally in text that is laid out from right to left. For example, U+0028 Left parenthesis is interpreted as opening parenthesis; in a left-to-right context it will appear as " (", while in a right-to-left context it will appear as the mirrored glyph ")".

Paired delimiters are mirrored even when they are used in unusual ways, as, for example, in the mathematical expressions $[\mathrm{a}, \mathrm{b})$ or $] \mathrm{a}, \mathrm{b}[$. If any of these expression is displayed from right to left, then the mirrored glyphs are used. Because of the difficulty in interpreting such expressions, authors of bidirectional text need to make sure that readers can determine the desired directionality of the text from context.

For some mathematical symbols, the "mirrored" form is not an exact mirror image. For example, the direction of the circular arrow in U+2232 Clockwise contour integral reflects the direction of the integration in coordinate space, not the text direction. In a right-to-left context, the integral sign would be mirrored, but the circular arrow would retain its direction. In a similar manner, the bidi-mirrored form of $\mathrm{U}+221 \mathrm{~B}$ cube root would be composed of a mirrored radix symbol with a non-mirrored digit " 3 ". For more information, see Unicode Technical Report \#25, "Unicode Support for Mathematics."

The list of mirrored characters appears in the Unicode Character Database. Note that mirroring is not limited to paired characters, but that any character with the mirrored property will need two mirrored glyphs-for example, U+222B integral. This requirement is necessary to render the character properly in a bidirectional context. It is the default behavior in Unicode text. (For more information, see the "Semantics of Paired Punctuation" subsection in Section 6.2, General Punctuation.)

This property is not to be confused with the related Bidi Mirroring Glyph property, an informative property, that can assist in rendering mirrored characters in a right-to-left context. For more information, see BidiMirroring.txt in the Unicode Character Database.

### 4.8 Name-Normative

Unicode characters have names that serve as unique identifiers for each character. The character names in the Unicode Standard are identical to those of the English-language edition of ISO/IEC 10646.

Where possible, character names are derived from existing conventional names of a character or symbol in English, but in many cases the character names nevertheless differ from traditional names widely used by relevant user communities. The character names of symbols and punctuation characters often describe their shape, rather than their function, because these characters are used in many different contexts.

Character names are listed in the code charts.
Stability. Once assigned, a character name is immutable. It will never be changed in subsequent versions of the Unicode Standard. Implementers and users can rely on the fact that a character name uniquely represents a given character.

Character Name Syntax. Unicode character names, as listed in the code charts, contain only uppercase Latin letters A through Z, digits, space, and hyphen-minus. In more detail, character names reflect the following rules:

R1 Only Latin capital letters $A$ to $Z(U+0041 . . U+0056), A S C I I$ digits $(U+0030 .$. $U+0039), U+0020$ SPACE, and $U+002 D$ HYPHEN-MINUS occur in character names.

## R2 Digits do not occur as the first character of a character name, nor immediately following a space character.

R3 U+002D HYphen-minus does not occur as the first or last character of a character name, immediately preceding a space character, nor immediately preceding or following another hyphen-minus character. (In other words, multiple occurrences of $U+002 \mathrm{D}$ in sequence are not allowed.)

## R4 A space does not occur as the first or last character of a character name, nor immediately preceding or following another space character. (In other words, multiple spaces in sequence are not allowed.)

See Appendix A, Notational Conventions, for the typographical conventions used when printing character names in the text of the standard.

Names as Identifiers. Character names are constructed so that they can easily be transposed into formal identifiers in another context, such as a computer language. Because Unicode character names do not contain any underscore (" ") characters, a common strategy is to replace any hyphen-minus or space in a character name by a single "_" when constructing a formal identifier from a character name. This strategy automatically results in a syntactically correct identifier in most formal languages. Furthermore, such identifiers are guaranteed to be unique, because of the special rules for character name matching.

Character Name Matching. When matching identifiers transposed from character names, it is possible to ignore case, whitespace, and all medial hyphen-minus characters (or any "_" replacing a hyphen-minus), except for the hyphen-minus in U+1180 HANGUL JUNGSEONG oe, and still result in a unique match. For example, "ZERO WIDTH SPACE" is equivalent to "zero-width-space" or "ZERO_WIDTH_SPACE" or "ZeroWidthSpace". However, "TIBETAN LETTER A" should not match "TIBETAN LETTER -A", because in that instance the hyphen-minus is not medial between two letters, but is instead preceded by a space. For more information on character name matching, see Section 5.7, "Matching Rules" in Unicode Standard Annex \#44, "Unicode Character Database."

Named Character Sequences. Occasionally, character sequences are also given a normative name in the Unicode Standard. The names for such sequences are taken from the same namespace as character names, and are also unique. For details, see Unicode Standard Annex \#34, "Unicode Named Character Sequences." Named character sequences are not listed in the code charts; instead, they are listed in the file NamedSequences.txt in the Unicode Character Database.

The names for named character sequences are also immutable. Once assigned, they will never be changed in subsequent versions of the Unicode Standard.

Character Name Aliases. Sometimes errors in a character name are discovered after publication. Because character names are immutable, such errors are not corrected by changing the names. However, in some limited instances (as for obvious typos in a character name), the Unicode Standard publishes an additional, corrected name as a normative character name alias. (See Definition D5 in Section 3.3, Semantics.) Character name aliases are immutable once published and are also guaranteed to be unique in the namespace for character names. A character may, in principle, have more than one normative character name alias.

Character name aliases are listed in the code charts, using a special typographical convention explained in Section 17.1, Character Names List. They are also separately listed in the file NameAliases.txt in the Unicode Character Database.

A normative character name alias is distinct from the informative aliases listed in the code charts. Informative aliases merely point out other common names in use for a given character. Informative aliases are not immutable and are not guaranteed to be unique; they therefore cannot serve as an identifier for a character. Their main purposes are to help readers of the standard to locate and to identify particular characters.

## Unicode Name Property

Formally, the character name for a Unicode character is the value of the normative character property, "Name". Most Unicode character properties are defined by enumeration in
one of the data files of the Unicode Character Database, but the Name property is instead defined in part by enumeration and in part by rule. A significant proportion of Unicode characters belong to large sets, such as Han ideographs and Hangul syllables, for which the character names are best defined by generative rule, rather than one-by-one naming.

Formal Definition of the Name Property. The Name property (short alias: "na") is a string property, defined as follows:

- For Hangul syllables, the Name property value is derived by rule, as specified in Section 3.12, Conjoining Jamo Behavior, under "Hangul Syllable Name Generation," by combining a fixed prefix and appropriate values of the Jamo_Short_Name property. For example, the name of U+D4DB is hangul syllable pWilh, constructed by concatenation of "HANGUL syllable" and three Jamo_Short_Name property values, "p" + "WI" + "LH".
- For ideographs, the Name property value is derived by concatenating the string "CJK UNIFIED IDEOGRAPH-" or "CJK COMPATIBILITY IDEOGRAPH-" to the code point, expressed in hexadecimal, with the usual 4- to 6-digit convention. For example, the name of $U+4 \mathrm{E} 00$ is cJk unified ideograph-4Eoo. Field 1 of the UnicodeData.txt data file uses a special convention to indicate the ranges of ideographs for which the Name property is derived by rule.
- For all other Graphic characters and for all Format characters, the Name property value is as listed in Field 1 of UnicodeData.txt. For example, U+0A15 GURmUKhi Letter ka or U+200D zero width joiner.
- For all other Unicode code points of all other types (Control, Private-Use, Surrogate, Noncharacter, and Reserved), the value of the Name property is the null string. In other words, na="".

The generic term "character name" refers to the Name property value for an encoded Unicode character. An expression such as, "The reserved code point U+30000 has no name," is shorthand for the more precise statement that the reserved code point $\mathrm{U}+30000$ (as for all code points of type Reserved) has a property value of na="" for the Name property.

Name Uniqueness. The Unicode Name property values are unique for all non-null values, but not every Unicode code point has a unique Unicode Name property value. Furthermore, because Unicode character names, character name aliases, and named character sequences constitute a single, unique namespace, the Name property value uniqueness requirement applies to all three kinds of names.
Interpretation of Field 1 of UnicodeData.txt. Where Field 1 of UnicodeData.txt contains a string enclosed in angle brackets, " $<$ " and " $>$ ", such a string is not a character name, but a meta-label indicating some other information-for example, the start or end of a character range. In these cases, the Name property value for that code point is either empty (na="") or is given by one of the rules described above. In all other cases, the value of Field 1 (that is, the string of characters between the first and second semicolon separators on each line) corresponds to the normative value of the Name property for that code point.

Control Codes. The Unicode Standard does not define character names for control codes (characters with General_Category=Cc). In other words, all control codes have a property value of na="" for the Name property. Control codes are instead listed in UnicodeData.txt with a special label " $<$ control $>$ " in Field 1. This value is not a character name, but instead indicates the code point type (see Definition D10a in Section 3.4, Characters and Encoding). For control characters, the values of the informative Unicode 1.0 name property (Unicode_1_Name) in Field 10 match the names of the associated control functions from ISO/IEC 6429. (See Section 4.9, Unicode 1.0 Names.)

## Code Point Labels

To provide unique, meaningful labels for code points that do not have character names, the Unicode Standard uses a convention for code point labeling.

For each code point type without character names, code point labels are constructed by using a lowercase prefix derived from the code point type, followed by a hyphen-minus and then a 4 - to 6 -digit hexadecimal representation of the code point. The label construction for the five affected code point types is illustrated in Table 4-12.

## Table 4-12. Construction of Code Point Labels

| Type | Label |
| :--- | :--- |
| Control | control-NNNN |
| Reserved | reserved-NNNN |
| Noncharacter | noncharacter-NNNN |
| Private-Use | private-use-NNNN |
| Surrogate | surrogate-NNNN |

To avoid any possible confusion with actual, non-null Name property values, constructed Unicode code point labels are often displayed between angle brackets: <control-0009>, <noncharacter-FFFF>, and so on. This convention is used consistently in the data files for the Unicode Character Database.

A constructed code point label is distinguished from the designation of the code point itself (for example, "U+0009" or "U+FFFF"), which is also a unique identifier, as described in Appendix A, Notational Conventions.

## Use of Character Names in APIs and User Interfaces

Use in APIs. APIs which return the value of a Unicode "character name" for a given code point might vary somewhat in their behavior. An API which is defined as strictly returning the value of the Unicode Name property (the "na" attribute), should return a null string for any Unicode code point other than graphic or format characters, as that is the actual value of the property for such code points. On the other hand, an API which returns a name for Unicode code points, but which is expected to provide useful, unique labels for unassigned, reserved code points and other special code point types, should return the value of the Unicode Name property for any code point for which it is non-null, but should otherwise construct a code point label to stand in for a character name.

User Interfaces. A list of Unicode character names may not always be the most appropriate set of choices to present to a user in a user interface. Many common characters do not have a single name for all English-speaking user communities and, of course, their native name in another language is likely to be different altogether. The names of many characters in the Unicode Standard are based on specific Latin transcription of the sounds they represent. There are often competing transcription schemes. For all these reasons, it can be more effective for a user interface to use names that were translated or otherwise adjusted to meet the expectations of the targeted user community. By also listing the formal character name, a user interface could ensure that users can unambiguously refer to the character by the name documented in the Unicode Standard.

### 4.9 Unicode 1.0 Names

The Unicode_1_Name property is an informative property referring to the name of characters in Version 1.0 of the Unicode Standard. Values of the Unicode_1_Name property are provided in UnicodeData.txt in the Unicode Character Database in cases where the Version 1.0 name of a character differed from the current name of that character. A significant number of names for Unicode characters in Version 1.0 were changed during the process of merging the repertoire of the Unicode Standard with ISO/IEC 10646 in 1991. Character name changes are now strictly prohibited by the Unicode Character Encoding Stability Policy, and no character name has been changed since Version 2.0.

The Version 1.0 names are primarily of historic interest regarding the early development of the Unicode Standard. However, where a Version 1.0 character name provides additional useful information about the identity of a character, it is explicitly listed in the code charts. For example, U+00B6 pilcrow sign has its Version 1.0 name, paragraph sign, listed for clarity.

The status of the Unicode_1_Name property values in the case of control codes differs from that for other characters. The Unicode Standard, Version 1.0, gave names to the C0 control codes, $\mathrm{U}+0000 . . \mathrm{U}+001 \mathrm{~F}, \mathrm{U}+007 \mathrm{~F}$, based on then-current practice for reference to ASCII control codes. Unicode 1.0 gave no names to the C 1 control codes, $\mathrm{U}+0080 . . \mathrm{U}+009 \mathrm{~F}$. The values of the Unicode_1_Name property have been updated for the control codes to reflect the ISO/IEC 6429 standard names for control functions. Those names can be seen as annotations in the code charts. In a few instances, because of updates to ISO/IEC 6429, those names may differ from the names that actually occurred in Unicode 1.0. For example, the Unicode 1.0 name of $\mathrm{U}+0009$ was horizontal tabulation, but the ISO/IEC 6429 name for this function is character tabulation, and the commonly used alias is, of course, merely tab.

### 4.10 Letters, Alphabetic, and Ideographic

Letters and Syllables. The concept of a letter is used in many contexts. Computer language standards often characterize identifiers as consisting of letters, syllables, ideographs, and digits, but do not specify exactly what a "letter," "syllable," "ideograph," or "digit" is, leaving the definitions implicitly either to a character encoding standard or to a locale specification. The large scope of the Unicode Standard means that it includes many writing systems for which these distinctions are not as self-evident as they may once have been for systems designed to work primarily for Western European languages and Japanese. In particular, while the Unicode Standard includes various "alphabets" and "syllabaries," it also includes writing systems that fall somewhere in between. As a result, no attempt is made to draw a sharp property distinction between letters and syllables.
Alphabetic. The Alphabetic property is a derived informative property of the primary units of alphabets and/or syllabaries, whether combining or noncombining. Included in this group would be composite characters that are canonical equivalents to a combining character sequence of an alphabetic base character plus one or more combining characters; letter digraphs; contextual variants of alphabetic characters; ligatures of alphabetic characters; contextual variants of ligatures; modifier letters; letterlike symbols that are compatibility equivalents of single alphabetic letters; and miscellaneous letter elements. Notably, U+00AA feminine ordinal indicator and U+00BA masculine ordinal indicator are simply abbreviatory forms involving a Latin letter and should be considered alphabetic rather than nonalphabetic symbols.

Ideographic. The Ideographic property is an informative property defined in the Unicode Character Database. The Ideographic property is used, for example, in determining line breaking behavior. Characters with the Ideographic property include Unified CJK Ideographs, CJK Compatibility Ideographs, and characters from other blocks-for example, $\mathrm{U}+3007$ ideographic number zero and U+3006 ideographic closing mark. For more information about Han ideographs, see Section 12.1, Han. For more about ideographs and logosyllabaries in general, see Section 6.1, Writing Systems.

### 4.11 Properties Related to Text Boundaries

The determination of text boundaries, such as word breaks or line breaks, involves contextual analysis of potential break points and the characters that surround them. Such an analysis is based on the classification of all Unicode characters by their default interaction with each particular type of text boundary. For example, the Line_Break property defines the default behavior of Unicode characters with respect to line breaking.
A number of characters have special behavior in the context of determining text boundaries. These characters are described in more detail in the subsection on "Line and Word Breaking" in Section 16.2, Layout Controls. For more information about text boundaries and these characters, see Unicode Standard Annex \#14, "Unicode Line Breaking Algorithm," and Unicode Standard Annex \#29, "Unicode Text Segmentation."

### 4.12 Characters with Unusual Properties

The behavior of most characters does not require special attention in this standard. However, the characters in Table 4-13 exhibit special behavior. Many other characters behave in special ways but are not noted here, either because they do not affect surrounding text in the same way or because their use is intended for well-defined contexts. Examples include the compatibility characters for block drawing, the symbol pieces for large mathematical operators, and many punctuation symbols that need special handling in certain circumstances. Such characters are more fully described in the following chapters.

Table 4-13. Unusual Properties

| Function | Description | Code Point and Name |
| :---: | :---: | :---: |
| Fraction formatting | Section 6.2 | 2044 fraction Slash |
| Special behavior with nonspacing marks | Section 2.11, Section 6.2, and Section 16.2 | $\begin{aligned} & \text { 0020 SPACE } \\ & \text { 00A0 NO-BREAK SPACE } \end{aligned}$ |
| Double nonspacing marks | Section 7.9 | 035C combining double breve below <br> 035D combining double breve <br> 035E combining double macron <br> 035 F combining double macron below <br> 0360 combining double tilde <br> 0361 combining double inverted breve <br> 0362 combining double rightwards arrow BELOW <br> 1DCD combining double circumflex above |
