WHAT IS OAUTH 2.0?

From the spec (RFC6749)

The OAuth 2.0 authorization framework enables a third-party application to obtain limited access to an HTTP service, either on behalf of a resource owner by orchestrating an approval interaction between the resource owner and the HTTP service, or by allowing the third-party application to obtain access on its own behalf.

The good bits

The OAuth 2.0 authorization framework enables a **third-party application** to **obtain limited access** to an **HTTP service**, either **on behalf of a resource owner** by orchestrating an approval interaction between the resource owner and the HTTP service, or by allowing the third-party application to obtain access on its own behalf.

In other words

OAuth 2.0 is a **delegation protocol** that lets people **allow applications** to **access things** on their behalf.

Who is involved?

The resource owner

- Has access to some resource or API
- Can delegate access to that resource or API
- Usually has access to a web browser
- Usually is a person

The protected resource

- Web service (API) with security controls
- Protects things for the resource owner
- Shares things on the resource owner's request

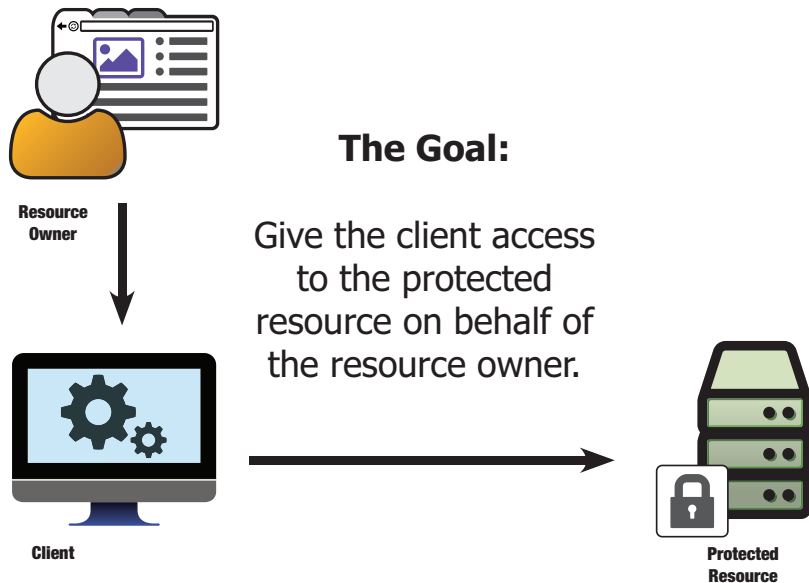

The client application

- Wants to access the protected resource
- Does things on the resource owner's behalf
- Could be a web server
 - But it's still a "client" in OAuth parlance
 - Could also be a native app or JS app

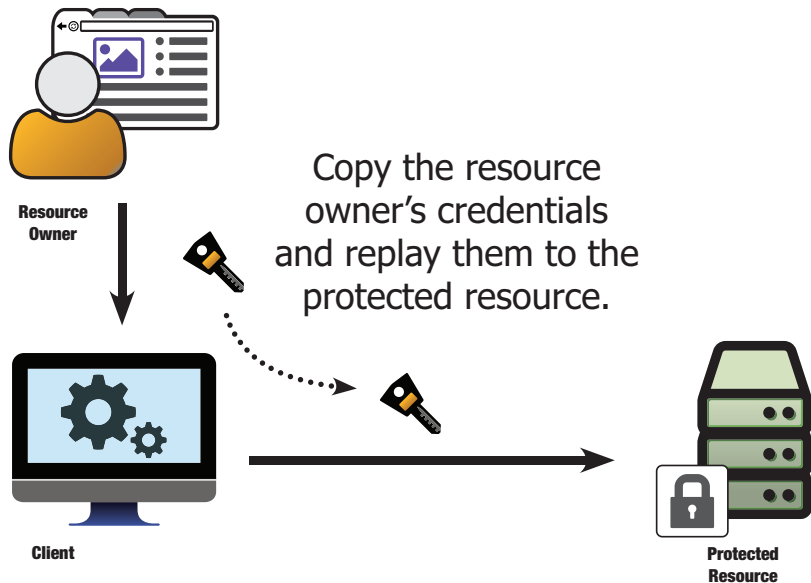

What are we trying to solve?

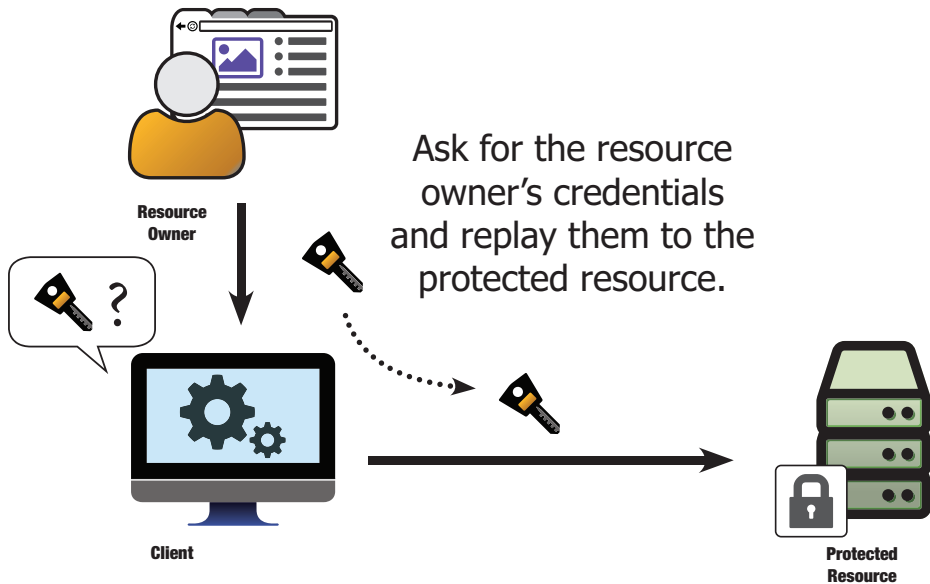

THIS ISN'T A NEW PROBLEM

People have been solving this for a long time

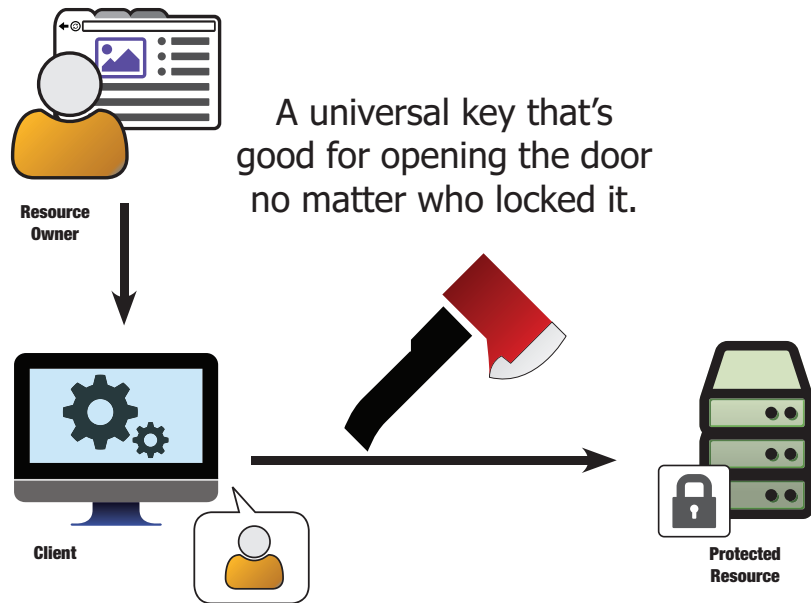

Steal the keys

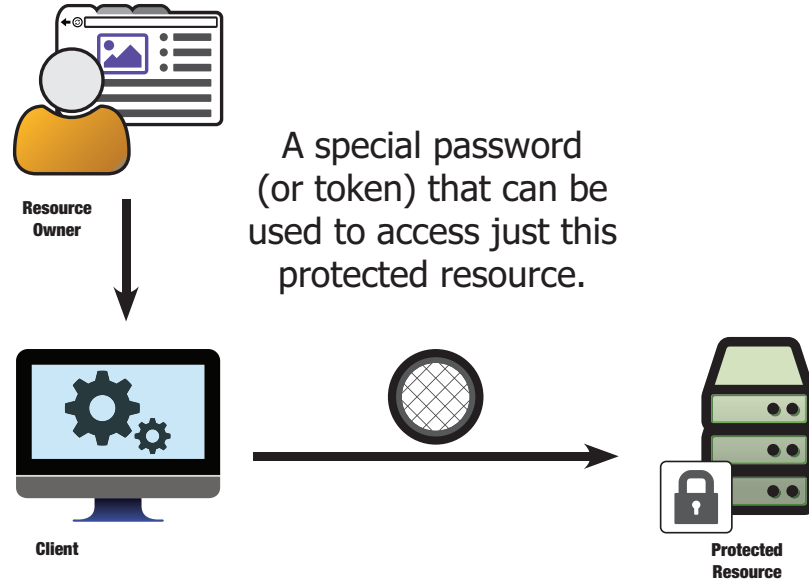

Ask for the keys

Use a universal key

Service-specific credentials

WE'RE GETTING CLOSER...

Introducing the Authorization Server (AS)

Resource Owner

The Authorization Server gives us a mechanism to bridge the gap between the client and the protected resource

Authorization Server

Client

Protected Resource

The Authorization Server

- Generates tokens for the client
- Authenticates resource owners (users)
- Authenticates clients
- Manages authorizations

OAuth Tokens

- Represent granted delegated authorities
 - From the resource owner to the client for the protected resource
- Issued by authorization server
- Used by client
 - Format is opaque to clients
- Consumed by protected resource

You've used OAuth

OAuth in Action: **OAuth Authorization Server**

Approve this client?

client_id: `oauth-client-1`

The client is requesting access to the following:

- read
- write
- delete

Approve

Deny

A BRIEF HISTORY OF OAUTH 2.0

Circa 2006

- HTTP password authentication common for API access
 - “Give me your password”
- Internet companies have proprietary solutions for delegated access
 - BBAuth, AuthSub, a few others

The problem

- Two smaller sites want to connect their APIs for their users
- Both use OpenID for login
 - No username/password to pass!
- Neither wants to use a proprietary solution

A new standard is born

- OAuth 1.0 is published independently
 - No formal standards body, people just use it
- A session fixation attack is found and fixed
 - New version is called OAuth 1.0a
- This community document is standardized as **RFC5849** in the IETF

People start using it

- OAuth 1.0a solves major pain points for many people in a standard and understandable way
- Google, Yahoo, and others replace their solutions with the new standard

People start abusing it

- People also decide to start using OAuth for off-label use cases
 - Native applications
 - No user in the loop
 - Distributed authorization systems

Version 2.0: The framework

- Modularized concepts
- Separated previously conflated components
- Added explicit extensibility points
- Removed pain points of implementers
- Standardized in [RFC6749](#) and [RFC6750](#)

What does this mean?

- Instead of a single protocol, OAuth 2.0 defines common concepts and components and different ways to mix them together
- It's not a single standard, it's a set of standards for different use cases

WHAT OAUTH ISN'T

Not defined outside of HTTP

- Core protocol defined only for HTTP
- Relies on TLS for securing messages
- There are efforts to use OAuth over non-HTTP protocols
 - GSSAPI
 - CoAP

Not an authentication protocol

- Relies on authentication in several places
 - Client authentication to token endpoint
 - Resource owner authentication at authorization endpoint
- Doesn't communicate anything about the user
- However: authentication protocols can be built using OAuth (OpenID Connect)

No user-to-user delegation

- Allows a user to delegate to a piece of software but not to another user
- However, multi-party delegation can be built using OAuth as a core component (UMA)

No authorization processing

- Tokens can represent scopes and other authorization information
- Processing of this information is up to the resource server
- However, several methods (UMA, JWT, introspection) to communicate this information

No token format

- Token is opaque to the client
- Token needs to be issued by the authorization server and understood by the resource server, but they're free to use whatever format they want
- However, JSON Web Tokens (JWT) provide a useful common format

No cryptographic methods

- Core OAuth relies on TLS for protecting information in transit
- However, other mechanisms like JSON Object Signing and Encryption (JOSE) define things that can be used with OAuth

Not a single protocol

- OAuth 2.0 is a *framework*
 - Several core flows plus extensions
- Two things can “implement OAuth” but be incompatible with each other
- However, code re-use and patterns between common components makes life simpler

THE AUTHORIZATION CODE FLOW

A deep dive into the canonical OAuth 2.0 transaction

The pieces of OAuth

**Resource
Owner**

**Authorization
Server**

**Access
Token**

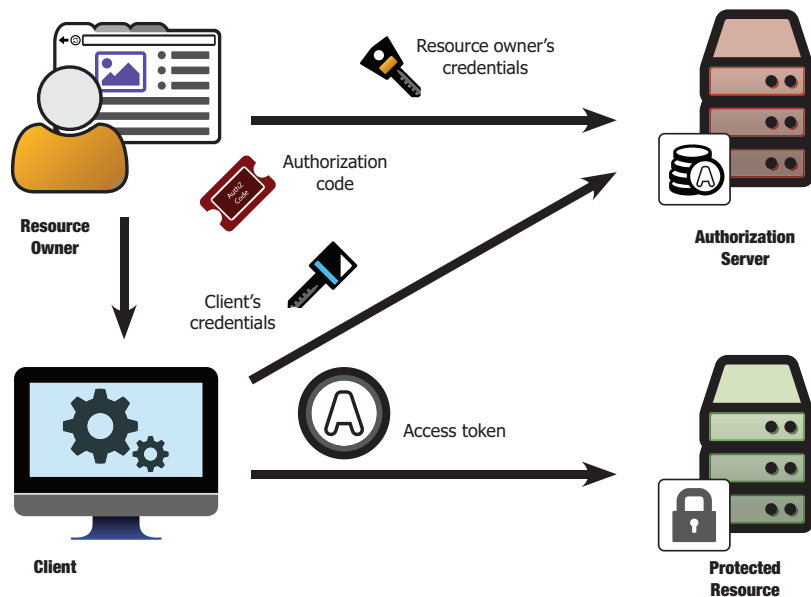

Client

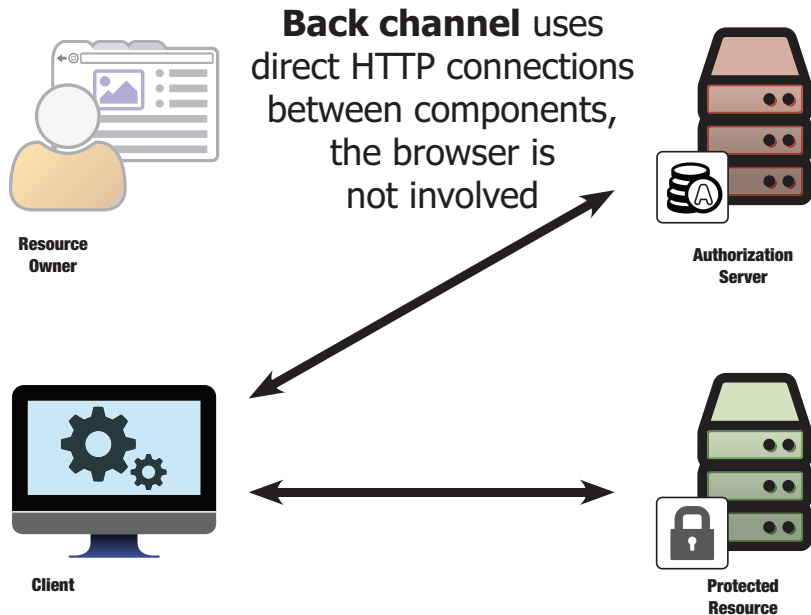

**Protected
Resource**

The authorization code flow

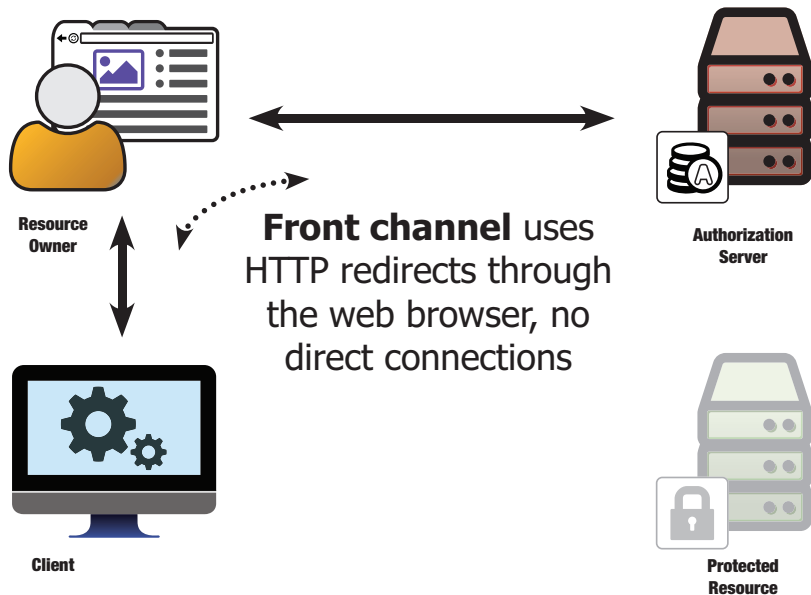

TWO FORMS OF COMMUNICATION

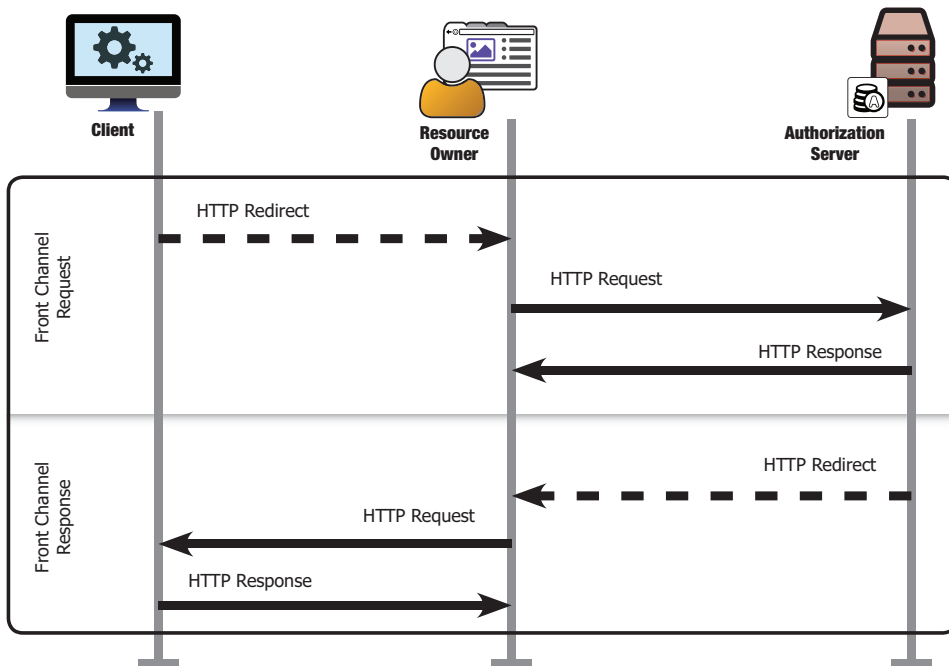

The back channel

The front channel

A front channel request/response

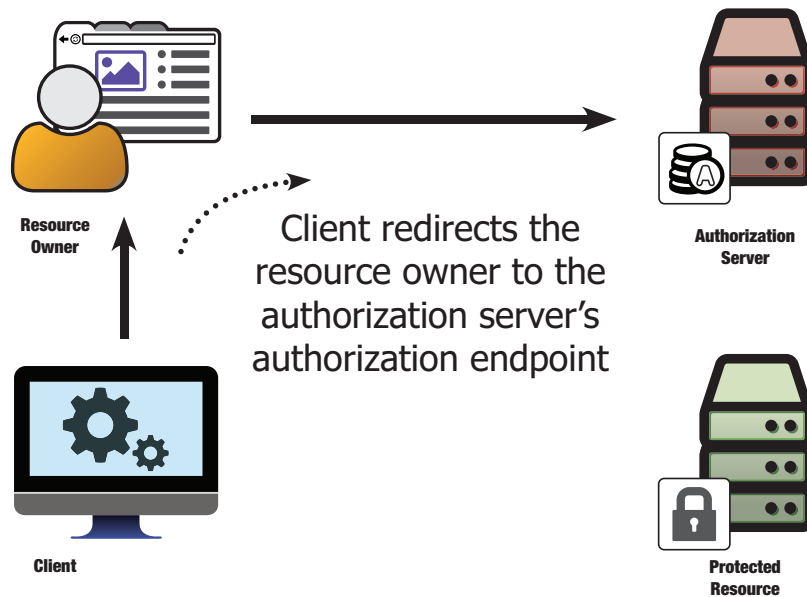

Why both?

- Separation of information
- Front channel when the user's involved
- Back channel when they're not

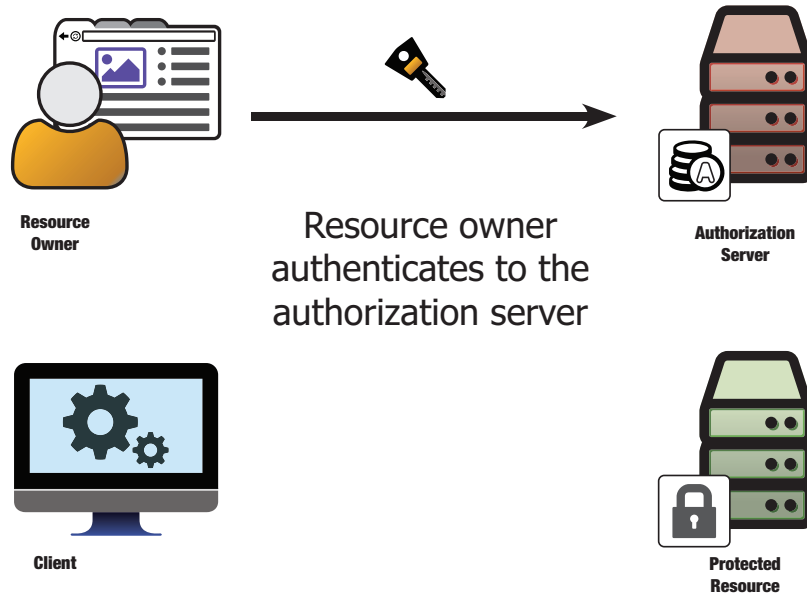

THE AUTHORIZATION CODE FLOW

Step by step

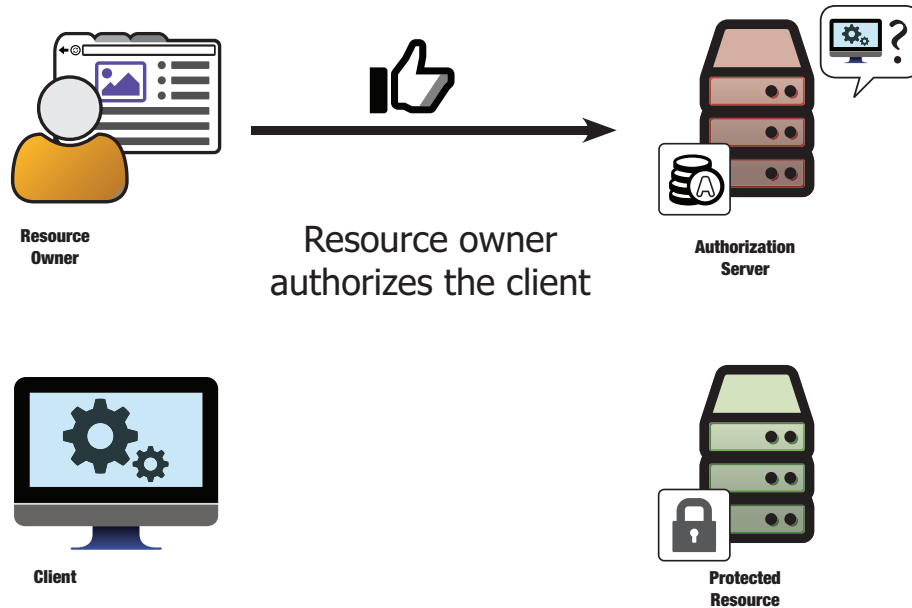

Authorization Code: Step 1

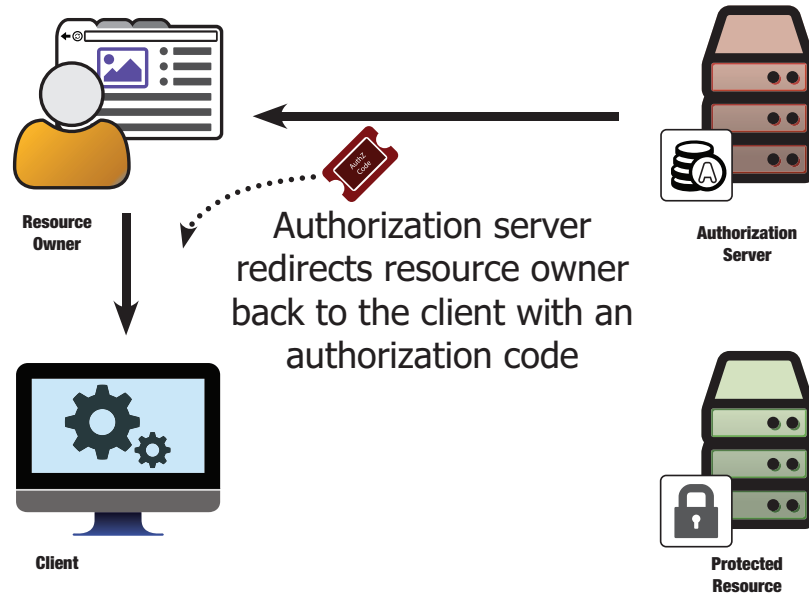

Authorization Code: Step 2

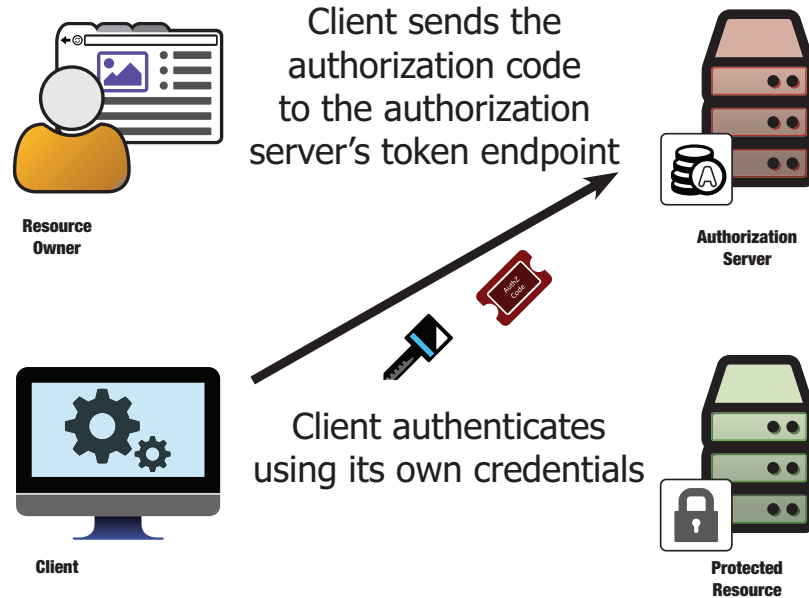

Authorization Code: Step 3

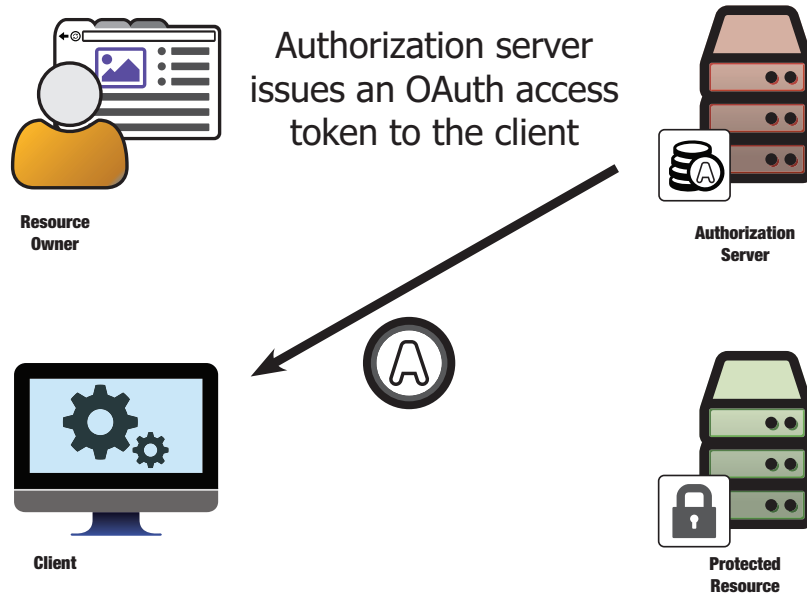

Authorization Code: Step 4

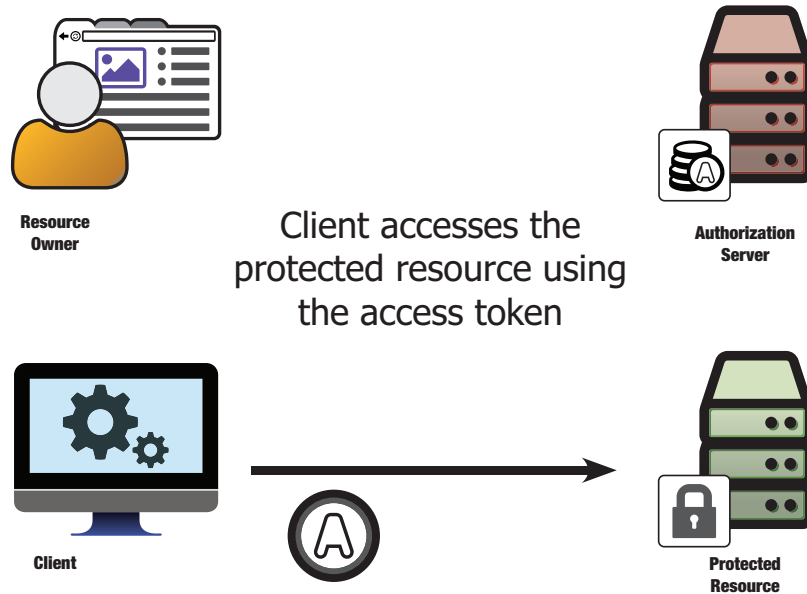

Authorization Code: Step 5

Authorization Code: Step 6

Authorization Code: Step 7

REFRESH TOKENS

When the user isn't there

- Access tokens work after the user leaves
 - One of the original design goals of OAuth
- What does a client do when the access token stops working?
 - Expiration
 - Revocation

Getting a new token

- Repeat the process of getting a token
 - Interactive grants: send the resource owner to the authorization endpoint
- But what if the user's not there anymore?

Refresh tokens

- Issued alongside the access token
- Used for getting new access tokens
 - Presented along with client credentials
 - Not good for calling protected resources directly

SCOPES

API Design

- Naïve APIs (like what we built) allow simple yes/no access
 - If your token is good, your request is good
- Smarter APIs divide access

Limited access

- Type of action
 - Read, write, delete
- Type of resource
 - Photos, metadata, profile
- Time of access
 - User is offline, limited number of accesses

OAuth Scopes

- Strings that represent what the token can do
- Client can ask for scopes
- Resource owner approves scopes
- Access token is bound to scopes

OTHER WAYS TO DO OAUTH 2.0

Protocol flexibility

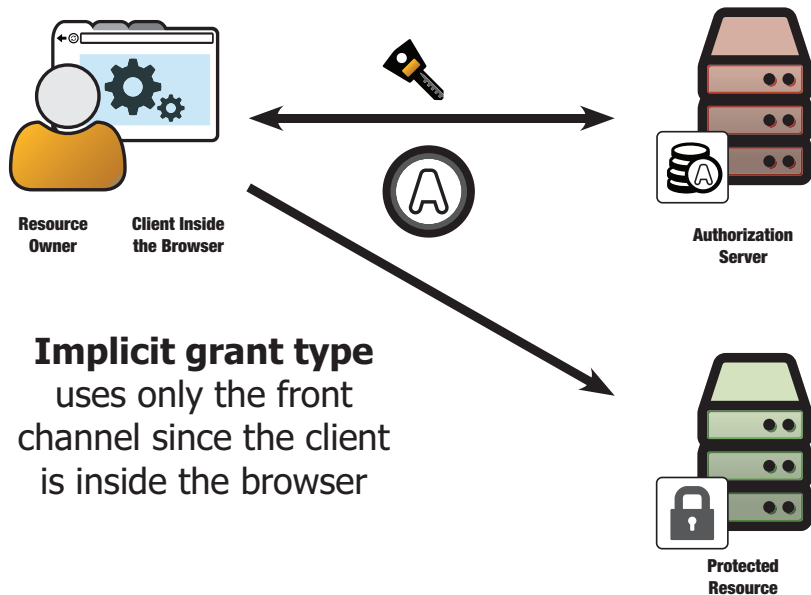

- Canonical use case: web server based application accessed through a browser
- Authorization code flow is built around this use case
- What about different kinds of clients?
- What about different kinds of delegation?

IMPLICIT FLOW

Stuff the client into the browser

- Authorization code flow keeps the token out of the browser and in the client
- But what if the client is *inside* the browser?

The implicit flow

Implicit grant type
uses only the front
channel since the client
is inside the browser

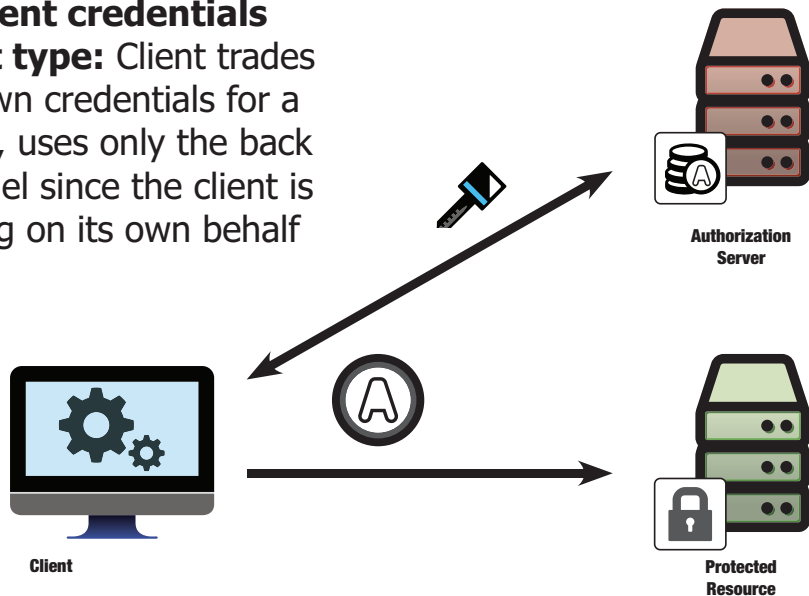

CLIENT CREDENTIALS FLOW

Client acts on its own behalf

- No explicit resource owner
- Replacement for API keys

The client credentials flow

Client credentials
grant type: Client trades its own credentials for a token, uses only the back channel since the client is acting on its own behalf

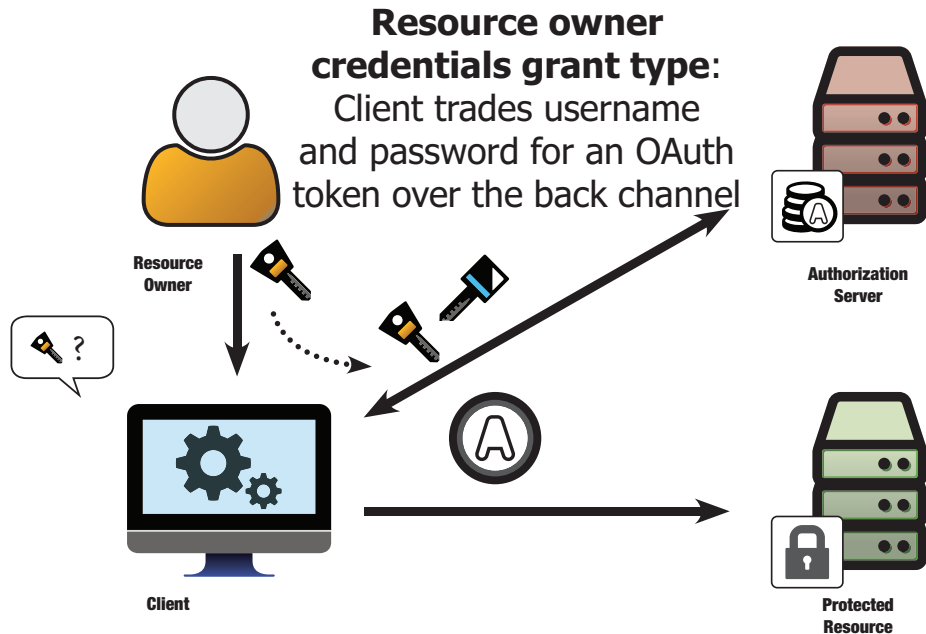

RESOURCE OWNER PASSWORD FLOW

Stealing the password

- Codify the anti-pattern: ask the user for their credentials and replay them
- Instead of saving the credentials, trade for an access token

The resource owner password flow

HOLD ON!

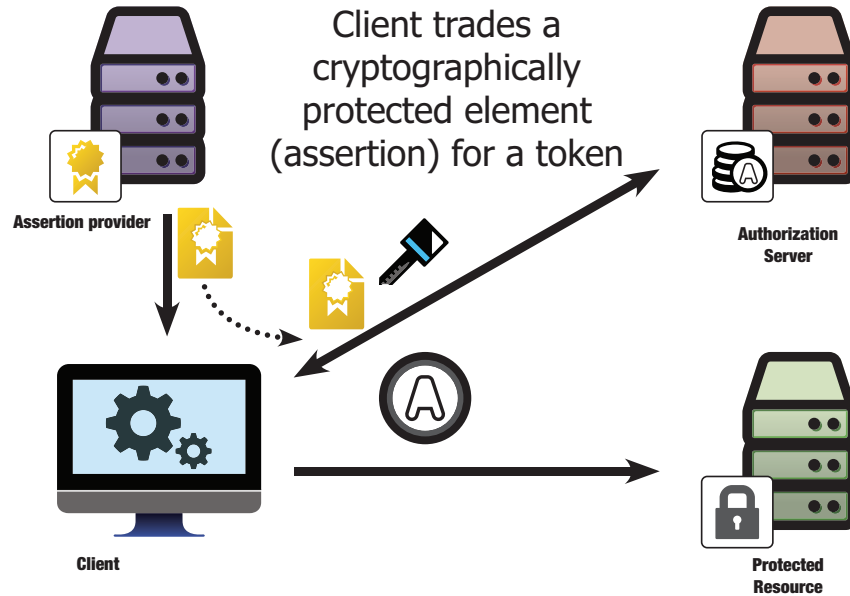

Didn't we say it was bad to steal the credentials?

ASSERTION FLOWS

Third-party authorization

- Have a trusted third party hand authorization to the client
- Client trades that for a token

The assertions flows

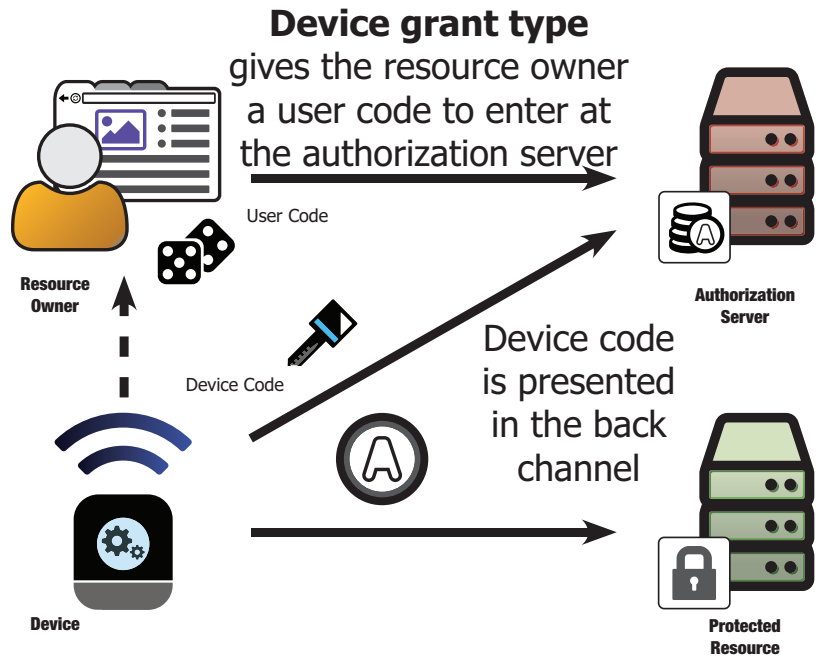

DEVICE FLOW

Limited interactivity

- Not every client has a web browser
 - Set-top boxes
 - Smart devices
- How do we get user interaction?
 - Split the pieces
 - Use the user to carry the information

The device flow

NATIVE CLIENTS

What's a native client?

- Runs on the end user's system
 - Not hosted on a remote web server
 - Not executed inside of a web browser
- Can be desktop or mobile
 - Local self-contained web server apps qualify

What makes a native client different?

- Functionality lives outside the browser
- Can't keep secrets from the user
 - Especially configure-time secrets
- Requires adaptations to redirect URI to use the front channel

Dealing with secrets

- Application is copied and run many times
 - Shouldn't give each copy the same secret
- Dynamic client registration
 - Give each instance its own ID and secret
- Public clients
 - Share an ID and don't use secrets

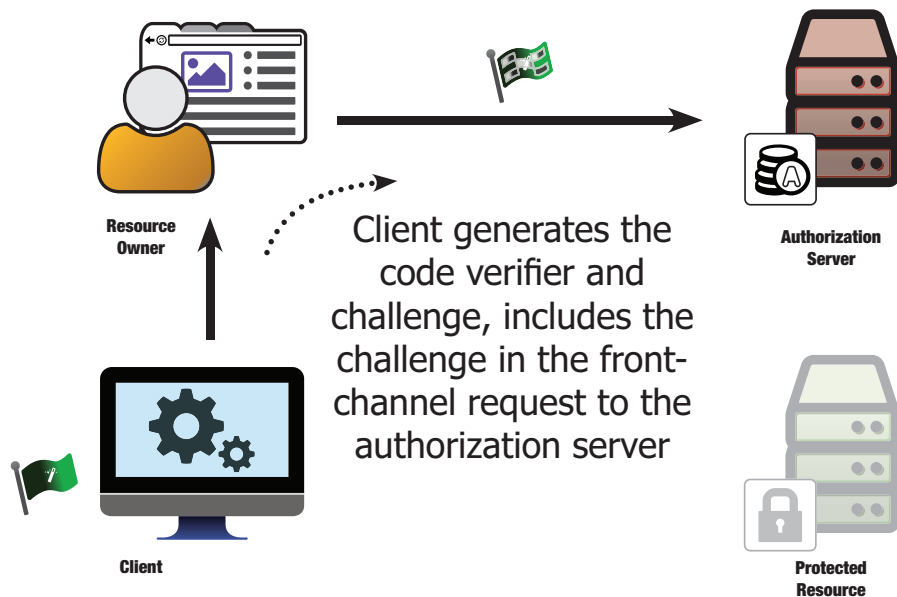

Redirect URIs

- Custom URI scheme
 - `myapp:/oauth_callback?code=ABC123`
- Locally hosted web server
 - `http://localhost:39103/myapp?code=ABC123`
- Remote host with push notification
 - `https://push.example.com/app-942/code=ABC123`

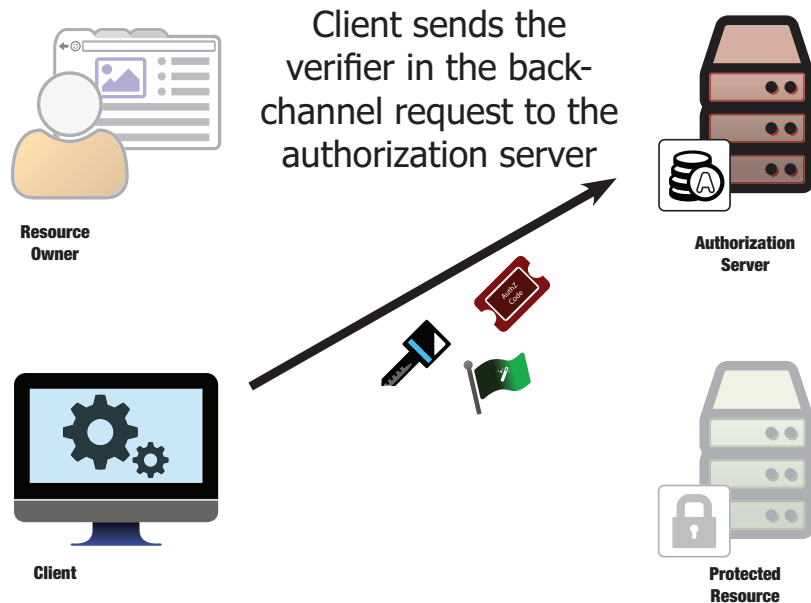

Redirect URIs with custom schemes

- Apps need to register for namespace
- Any app can take any namespace
- Malicious apps can try to grab items coming in on redirect URIs
 - Authorization codes (for code flow)
 - Tokens (for implicit flow)

PKCE: Sending the challenge

PKCE: Sending the verifier

PKCE: Verifying the challenge

**Resource
Owner**

**Authorization
Server**

Client

Authorization server
re-generates the
challenge from the
verifier and compares
it to the challenge
previously sent

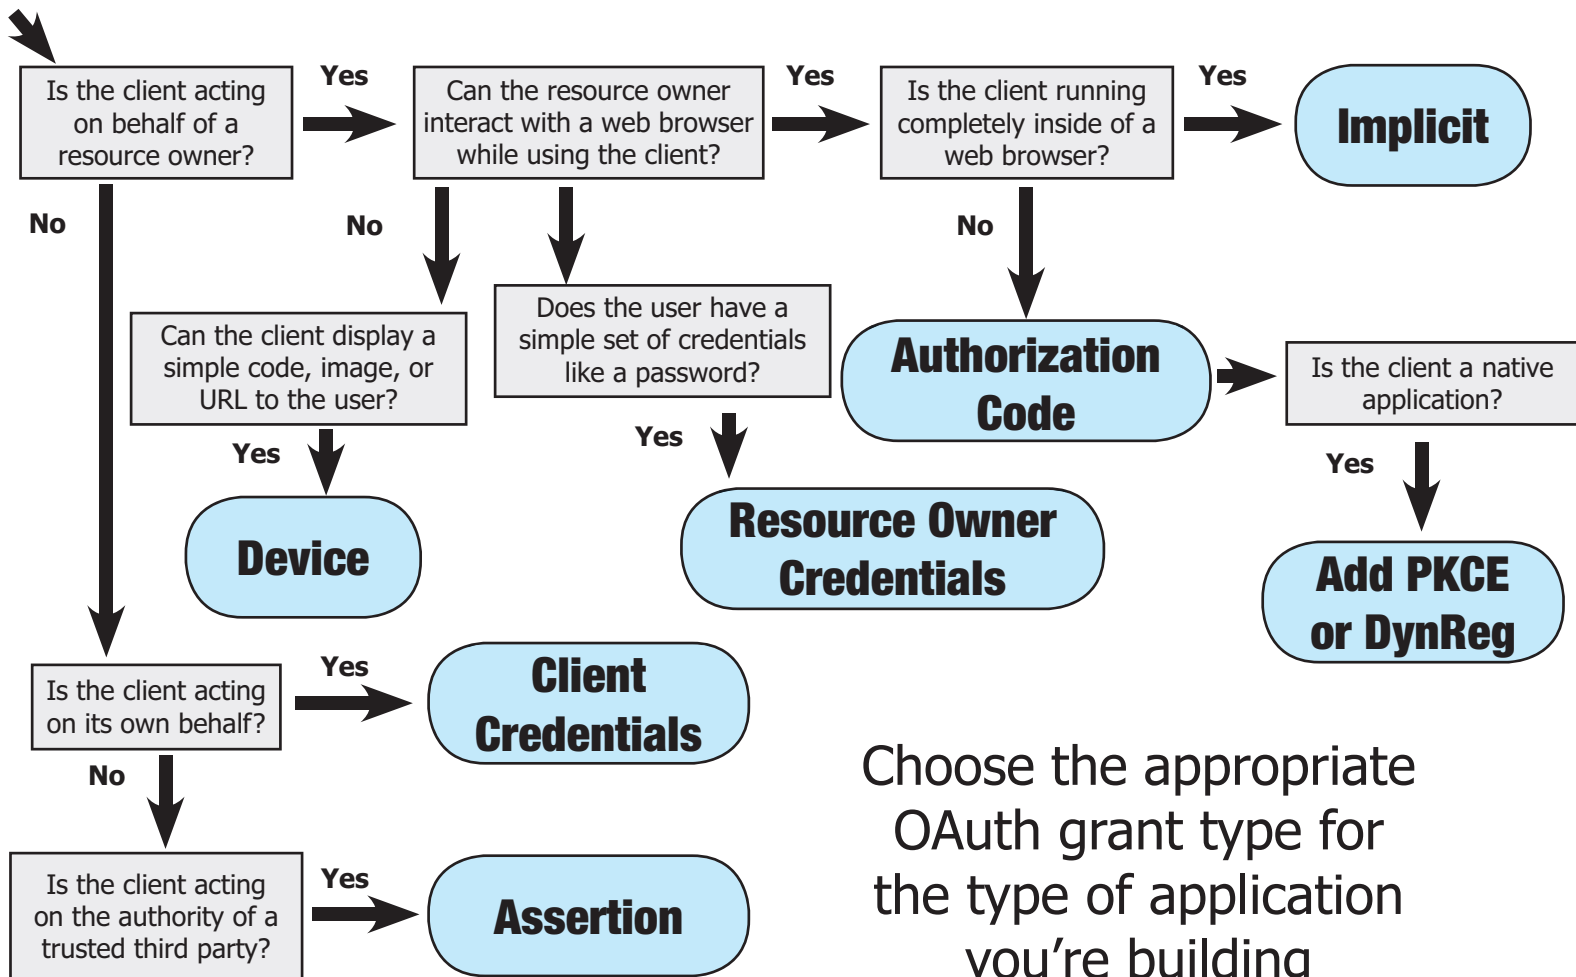

**Protected
Resource**

MANAGING THE GRANT TYPES

Different use cases

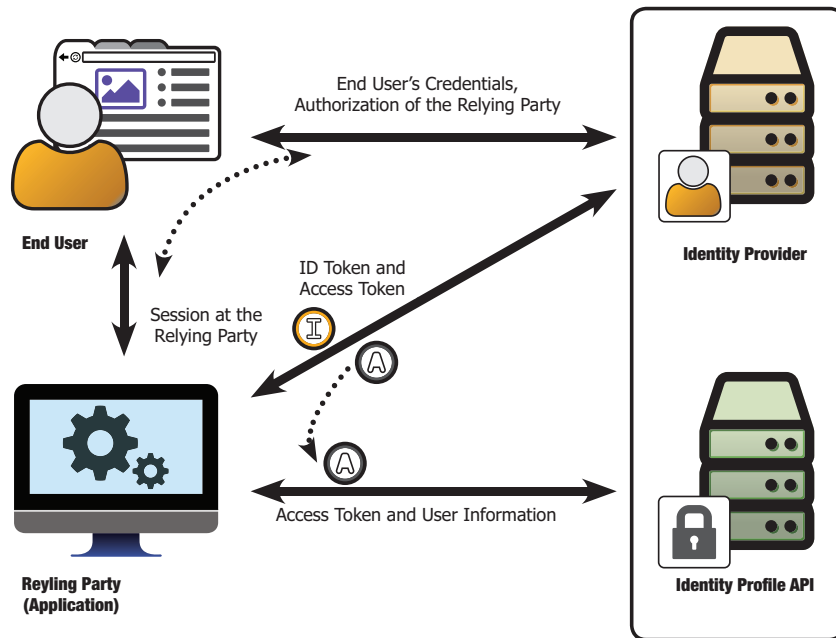

- Authorization code flow: web applications, some native applications
- Implicit flow: in-browser applications
- Client credentials flow: non-interactive
- Password flow: trusted legacy clients
- Assertion flows: trust frameworks

HOW TO CHOOSE A GRANT TYPE

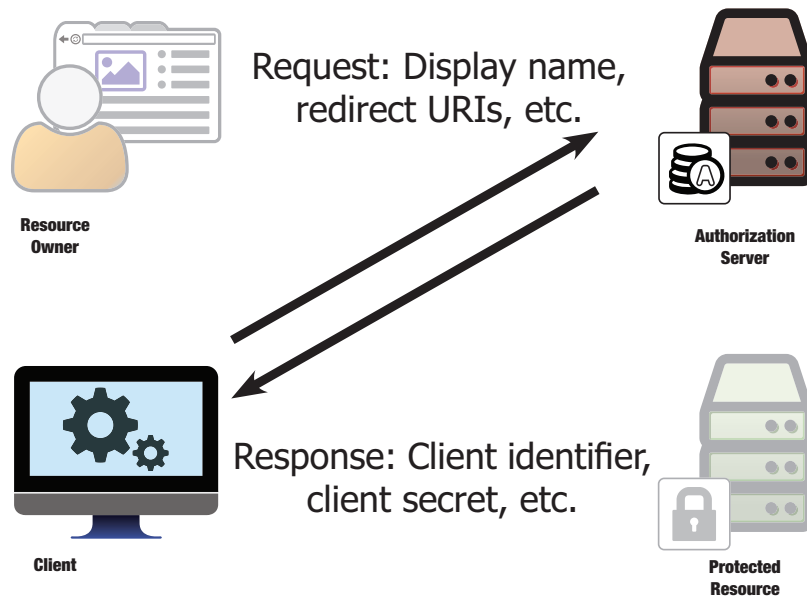

Choose the appropriate OAuth grant type for the type of application you're building

OpenID Connect

Dynamic Client Registration

Software statements

- Third party generates an assertion that contains fixed attributes of the client
 - Client can't change or override what's in the statement
- Client presents the statement alongside any variable attributes
- Server generates unique ID and secret for client

Why use a software statement?

- Many instances of a client software
 - Each instance needs its own ID/secret
 - All instances should be “recognizable”
- Allow pre-registration across domains
 - Software statement from trusted server
 - Individual AS registrations for clients

TOKEN INTROSPECTION

OAuth tokens are opaque

- But they're only opaque *to the client*
- Protected resource needs to know the token
 - What's it good for?
 - Who issued it?
 - Is it valid?

How does the resource know?

- Database lookup
 - AS and RS are in the same box
- Pack information into the token itself
 - Remember JWT?
- Query the AS
 - Runtime lookup over the network

“What’s this token good for?”

- Protected resource queries the AS about a token it received
- AS responds with a JSON structure describing the token’s status

Introspection trade-offs

- Requires extra credentials (at the RS)
- More network traffic
- Subject to cache consistency problems
 - Introspect every time? Only on timeout?

TOKEN REVOCATION

Completing the token lifecycle

- OAuth defines how to get a new token and refresh a dead token
- Revocation allows clients to proactively throw away tokens they no longer use

Why revoke tokens?

- Native application being uninstalled
- User selects “log out” or “de-authorize” from the client (not the AS)

A simple protocol

- Client POSTs to the revocation endpoint
 - Token included in body
- Server deletes the token if it finds it
- Server tells the client everything is OK
 - Even if no token was deleted, we pretend we did
 - Otherwise clients could use this to fish for token values
- Client throws out its copy of the token

POP, mTLS, AND TOKEN BINDING

Beyond bearer tokens

- Bearer tokens are sent as-is over the wire
- Anyone who has access to the token can use it
- Proof of Possession (PoP) tokens require cryptographic proof of a key
 - Token is transmitted as-is
 - Key is used to sign something, not transmitted itself

Two parts

Token:
Opaque to client
Associated with scopes and RO
Sent as-is to PR

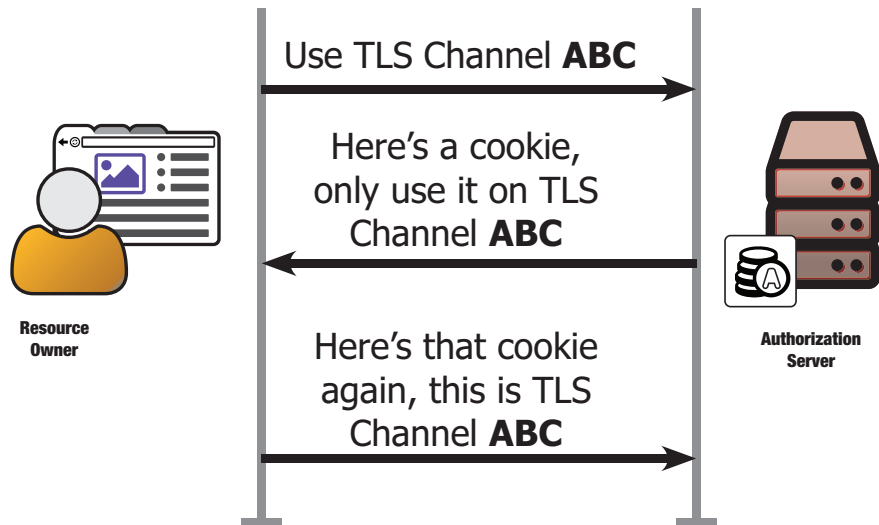

Key:
Known to client
Associated with token
Used to sign request

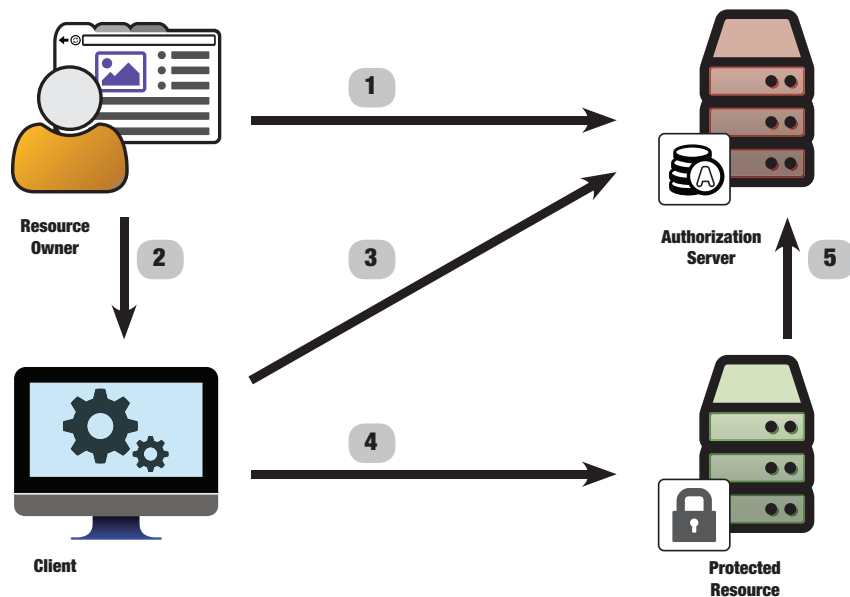

Mutual TLS

- Client presents certificate to token endpoint
- AS hashes certificate and ties it to token
- Client presents same certificate to RS
- RS hashes certificate and sees if it's the same as the one bound to the token
- Client *does not have to authenticate* with TLS

Token binding

A problem with token binding
